1. Name and address of reporting institution: Plant Breeding and Acclimatization Institute, Cereals Department, Cracow, Wróblewskiego 5.
2. Name of principal investigator: Professor Dr. Tadeusz Ruebenbauer.
3. Project title: Finding sources of resistance to loose smut in barley and identifying genes for resistance.
4. Project number: B-21-CR-18.
5. Grant number: FG-P0-129-61.
6. Dates of research period covered by report: From 1.I to 31.XII. 1962.

CONFIDENTIAL

50X1-HUM

CONFIDENTIAL**II. Summary.**

The aim of this work is to find, in various varieties of spring barley, genes causing the resistance to 2 groups of physiologic races of loose smut in barley occurring in Poland.

52 various cross combinations were made in order to find linkages between morphological characters of plants and their resistance to loose smut. Among these combinations the most part was new, but some of them were the replications of these crosses of 1961, which yielded too little hybrid grain.

The plants of the F₁ generation were not infected to investigate exactly the inheritance of morphological characters of these barley varieties, which were used for crosses.

For this purpose a thoroughly description of hybrid material was carried out and therefore the occurrence of some characters, not following strictly the laws of heredity, was observed.
This hybrid material will be then investigated.

Collaterally to the above mentioned work, the detailed description of the barley varieties, obtained from the USA, was carried out, to examine accurately the material, which will be used for crossings, in order to determine the VI and VII linkage groups.
Since the obtained samples were very small, this material was only increased in 1962.

During the flowering time of barley the infection of these varieties was carried out, which resistance to both groups of races of loose smut occurring in Poland, is hitherto unknown.

At the same time we are trying the simultaneous crossing and infecting the plants. If the results of this procedure are positive, we shall be able to test the resistance of loose smut as early as in the F₁ generation.

CONFIDENTIAL

III. Detailed report.**CONFIDENTIAL**1. Introduction.

Many scientists were trying to solve the problem of inheritance of resistance to loose smut in barley. This resistance, according to variety, may be conditioned by one or two pairs of independent genetic factors dominant or recessive.

Zeiner /17/ stated that resistance of varieties Blaue Nackte and Walpersii /except one cross/ depends on single gene, which was impossible to determine whether it was dominant or recessive.

In the highly susceptible cross: Walpersii x Heils Franken the resistance to loose smut was conditioned by two factors.

The resistance of variety Valentine to race marked by Vr was conditioned by single dominant gene marked by Un_1 /1,2/. This variety was susceptible to race Vs. Dominant genes Un_2 in Trebi variety and Un_3 in Jet variety caused the highest resistance /5,6,12,14/. Dominant homozygous genes Un_4 in Dorsett variety and Un_5 in line X-173-10-5-6-1 condition the resistance within the limits of 13-43 per cent, the same heterozygous genes cause the greater resistance within the limits of 55-65 per cent.

There are the possibility of linkage between genes Un_3 and Un_4 , which occurred in varieties Jet and Dorsett /4, 12/. The gene Un_4 belongs to the VI linkage group /7/.

The resistance of Jet variety to race Tr was conditioned by single dominant factor Un_6 /5,14/, or by two factors /8/.

The resistance of Anoidium variety to race Tr is caused by recessive gene un_7 , and to race Vo by dominant gene, probably Un_7 /1,2, 16/. Moreover other dominant genes for resistance to loose smut are known, but have not yet been determined e.g. in Ogaliteu variety - 1 dominant gene /16/, in Abyssinian variety -2 dominant genes, in Valki variety - 1 dominant gene /5/.

The morphological characters are inherited independently from the susceptibility to loose smut /10, 12/.

Nevertheless, according to Shands /13/ there is a connection between resistance to loose smut and resistance to rust in selected barley H-47-26 and according to Vavilow the resistance to Helminthosporium gramineum.

2. Experimental procedures.

The crossing procedure was as follows: the lemma was incised along central vein with a scalpel. Through this fissure the anthers were removed /castration/ or slipped in /pollination/. In many-rowed barley the side spikelets were removed. The awns were not removed neither in 2-rowed nor in many-rowed barleys in order not to disturb the biologic balance of crossed plants. The crossed

CONFIDENTIAL

spikes were isolated with ~~CONFIDENTIAL~~. The plants were infected through similar lemma fissure as made for crossing, where the smut spores were put on the stigmas with thin brush.

15 spikes of each variety were infected to obtain the highest possible number of infected grains, which made possible the exact estimation of investigated varieties.

The above mentioned method of infection is primitive and very laborious indeed, but very reliable. The percentage of smutted plants, caused by this method of infection in our previous work on identification of the races of loose smut, reached even 99.2,

The threshing of investigated material was carried out in December 1962, because it is known from literature data as well as from own practice that the earlier threshed seeds are characterized by lower germination power.

The description of morphological characters during the vegetative season as well as in laboratory was carried out as follows:

- a. the values of following characters: rachis internode length, plant hight, number of normal developed stems are given as an average of 5 measurements.
- b. the infection with Powdery Mildew was determined by 4- degree scale: 0 - no infection, 1 - weak, 2 - moderate, 3 - strong infection.
- c. the infection of rust occurred sporadically, therefore its intensity was not given.

The investigated material was strictly selected before the description of morphological characters began, in order to remove the plant derived from selfing.

Immediately after threshing the not infected grain was sown in the glasshouse in order to examine whether and when the heading should occur. The aim of investigating this problem is to grow two generations within a year, and by this means to accelerate the research course.

3. Results. The obtained results are showed in tables I, II and III. Morphological description of the varieties obtained from the USA in 1962 is not enclosed, since this material is well known there. The results concerning the possibility of simultaneous crossing and infecting the barley plants as well as the data concerning the susceptibility of these parental varieties to loose smut, which resistance to this pathogen is unknown, will have been given next year on account of biennial life cycle of the fungus.

~~CONFIDENTIAL~~

4. Discussion.

The number of obtained grain from the 52 cross combinations carried out in 1962 is given in table I. The cross combinations, which yielded too little grain i.e. 3, 5, 9, 20, 32, 44, 52 and 56 will be replicated next year.

The unsatisfactory seed setting was caused, in some instances, through late flowering of the pollen parents e.g. *Zeocrinum* - at 28.VI, *Hordeum hexastichon album monstrosum* - at 1.VII, *Werribee* 6-rowed at 27.VI, in comparison with the seed parents, which were ready for emasculation as early as 20.VI.

This inconvenience will be improved in current year by duly adjusted sowing terms.

The description of morphological characters of the F₁ generation of the crosses carried out in 1961 is given in table II.

In order to examine accurately the morphological characters of the parental varieties, this hybrid material could not be infected / as a result of infection with loose smut the spikes of barley are heavily damaged, therefore the determination of their characters is impossible/.

This assumption seems to be right, since in some cross combinations certain characters occurred/marked in table II by x/, which do not follow accurately the laws of heredity.

In order to explain this problem these characters will be investigated again. To provide the better illustration of inheritance of studied characters, the morphological description of parental varieties is given in table III.

5. Conclusions. On the base of the exact analysis of the I-st hybrid generation it was stated that some characters were irregularly inherited. This phenomenon occurred most often in these cross combinations, where the variety OAC 21 was used as seed parent, and in two instances, where other two many -rowed varieties/ Walpersii and Atlee/ were used for this purpose. It is difficult to decide what genetic factor conditions such a phenomenon, until it is exactly investigated.

6. Plan for future work.

- a. Replication of these cross combinations, which yielded too little grain in 1962.
- b. Replication of these cross combinations, where in the F₁ generation the irregularly inherited characters occurred.
- c. Making new crosses with the american varieties in order to determine the VI and VII linkage groups.

CONFIDENTIAL

- CONFIDENTIAL
- d. Replicating to test the susceptibility to loose smut of parental varieties, in which this character is hitherto unknown. Replicating the trial on possibility of simultaneous crossing and infecting the barley plants. These replications are necessary with respect to the influence of climatic conditions on the infection results in particular years, what was observed in our work on identification of groups of physiologic races of loose smut.
 - e. Investigating the susceptibility to loose smut of the varieties obtained from the USA.
 - f. Infecting with loose smut the plants of the F₁ generation of crosses carried out in 1962.

| 36. | Black barley from Pervival x H. sativum furcatum distichum nigrum | - | - | - | leaves, black | a | smooth | 3.9 | 1-side spike | black | brittle |

Remarks:

1. The characters: rachis internode length, height of plant, number of normal developed stems are given as an average of 5 measurements.

2. The characters marked by /x occurred unexpectedly and are not connected with the habitus of parents.

3. The infection with Fowley's Mildew is determined by 4-degree scale: 0 - no infection, 1 - weak,

2 - moderate, 3 - strong infection.

4. The infection with rust occurred sporadically, therefore its intensity is not given.

5. The right side of this table ought to be put together with the left one.
