Provisional Report on Experiments to Improve the qualities of Aluminum Oxide as active white Filling Agent in Rubber lixtures

- 1. The purpose of this provisional report is to acquaint the technical personnel of the plant with the results of experiments made to find an improved aluminum oxide composition to be used as active filling agent. Research activities are not completed but the results achieved so far can be used as a basic method in the manufacturing procedure.
- 2. The first patent for the use of aluminum oxide as filling agent was applied for in 1941 by the Deutsche Cold- und Silberscheide-anstalt Firm. In this application aluminum oxide was mentioned as highly active filling agent for natural and synthetic rubber. By using aluminum oxide as the filling agent the tensile strength of butadien@rubber is increased to 208 kg/cm² and the strength limit is 462 percent.
- 5. In tests by Dr. Relles and Dr. Hauschulz in the Buna plant and tests by Dr. Pattok in the Farbenfabrik Wolfen, the addition of aluminum oxide (obtained from alum or aluminum sulphate) indicates an excessive degree of deformation (10,000 to 20,000 or more) although the solidity of the vulcanized material is increased (200-280 kg/cm²).

Rubber mixtures with such a high deformation degree cannot be processed in rubber plants. Therefore the industrial use of aluminum oxide as an active filling agent was not practicable in the form proposed by the Deutsche Gold- und Silberscheideanstalt Firm.

The value of aluminum oxide as filling material is also considerably reduced due to its excessive static stretch dilation (40 to 80 percent).

- 4. Dr. Nelles and Dr. Hauschulz made special tests to obtain aluminum oxide with a normal rate of mixture deformation. Small quantities of inorganic salts of alkali-metals and other metals were added to the sulphate before the heating process. The tests had no practical results. Although the degree of deformation declined, the tensile strength of the vulcanized material decreased considerably.
- 5. It is probable that the addition of alkali-salts at a heating temperature of 900° to 1,000° Cleads to the formation of nonactive meltings with aluminum oxide or favors sintering of aluminum oxide particles due to their size or shape or the condition of the surface, thus producing nonactive forms. Dr. Espich tried to solve the problem of the low degree of deformation by the same procedure. He also added various inorganic salts to the basic way material before heating. However, his tests did not lead to any positive results either.

The following data were listed in the experiments of Dr. Esrich:

Summarizing the mentioned tests aluminum oxide is not suitable as a filling agent in the proposed form. However, the research is significant as it proves. for the first time, that the tensile strength of vulcanized material is considerably increased by adding to the rubber mixture aluminum oxide obtained from alum or aluminum sulphate through disintegration at high temperature. Aluminum oxide can be used as active filling agent in the rubber industry only after the problem of reducing the degree of deformation to a normal figure (1,500 to 3,000) has been solved. By reducing the degree of deformation many other qualities of vulcanized materials are also improved (stretch, stretch dilation coefficient and so on). Our research work was done to solve this problem.

25X1 6. Description of experiments to improve the qualities of aluminum oxide.

25X1

Contrary to the experiments of Dr. Helles and Dr. Hauschulz to achieve the reduction of the degree of raw deformation by processing the finished aluminum oxide with organic substances and not by adding various inorganic substances to the raw material during aluminum oxide production.

a. The first method consists in adding softening agents to the mixtures in order to obtain a reduction of the degree of deformation. For this purpose parafflinic acid was added to the rubber mixture in quantities of 2, 3, 5 and 8 percent.

| SECHET- | |
|---------|--|
| | |

| SECRET/ | | | • |
|---------|--------------|--------|-------|
| CENTRAL | INTELLIGENCE | AGENCY | 25X1A |

The results show that by adding 2 percent of paraffinic acid only a slight decrease of the degree of deformation occurred. The addition of paraffinic acid in greater quantitles leads to a reduction of the degree of deformation and to a reduction of the tensile strength of vulcanized material (see table 3). This method was abandoned due to unsatisfactory results.

b. The second method consisted in covering the surface of the aluminum oxide with the layer of organic matter to decrease the friction between rubber and filling agent thus reducing the degree of raw deformation. This represents an absolutely new procedure in the rubber industry.

while examining silipur as an active filling agent, obtained through precipitation of silikosol sulphate by means of an ammoniacal solution of sodium sulphate, Dr. Pattok tried various materials to increase the moistening property of the filling agent in the rubber compound. The following materials were tested:

I.G. wax, chloric rubber, styrol, raw rubber, I.G. wax N (new) and benzyl cellulose. These materials were first dissolved in water or benzol and in this condition coated on the surface of the filling agent. As shown by the table below the used materials not only reduced the degree of solidity but also increased the degree of the deformation of the raw mixtures.

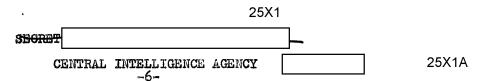

| Table 2 | |
|---------|--|
|---------|--|

| Filling materia <u>l</u> | Fill weigh | | o F | D | B1.D | E | Н |
|-------------------------------------------|---------------|-------|-----|-------------|------|----|----|
| Silica gel poweder/ silipur not processed | 13 | 5500 | 76 | 5 95 | 33 | 56 | 69 |
| Silipur 636 with IG wax suspension | 28 | 7050 | 19 | 330 | 29 | 57 | 69 |
| Silipur 638 with chloric rubber | 25 | 9050 | 24 | 275 | 36 | 57 | 73 |
| Silipur 693 with styrol solution | 20 | 11050 | 25 | 230 | 17 | 58 | 75 |
| Silipur 640 with raw rubber | 25 | 8550 | 22 | 309 | 33 | 57 | 69 |
| Silipur 642 with | 20 | 9550 | 22 | 320 | 29 | 54 | 74 |
| Silipur 644 with benzyl cellulose | 21 | 9050 | 22 | 335 | 35 | 56 | 72 |

These data show that the second method of solving the problem was at first a failure.

Approved For Release 2003/08/11: CIA-RDP82-00457R005100070009-3

c. At a meeting with the Chief Engineer General Kirpichnikov in charge, first engineer Khcheyan suggested, for the first time, obtaining a low degree of deformation by submitting the finished aluminum oxide to an additional process.

Tests were started to lower the degree of deformation of raw buna mixtures by processing aluminum oxide with organic matters. A simple procedure consisting of an additional treatment of Al₂O₃ with nekal EX₉ made in the laboratory of Engineer Zacharias proved this method to be correct. Several organic substances were then used in later tests.

7. Description of the experimental part.

Mixing formula No 92

Euna S 5 100 parts of weight Aluminum oxide 80 parts of weight Zine oxide 5 parts of weight Sulphur 2 parts of weight Vulkasit "A" 2 parts of weight

The aluminum exide containing mixture is rolled 15 to 20 minutes without additional treatment and 15 minutes after treatment.

The test results obtained after addition of 2 to 8 percent of paraffinic acid to the mixture are listed in table No 3:

Final conclusions

- l. Additions of 2 to 3 percent of paraffinic acid increase the solidity up to 250 kg/cm²; they improve the ductility decrease plasticity, and slightly reduce the degree of deformation.
- 2. After addition of 5 percent of paraffinic acid the tensile strength decreases, the ductility improves, and the degree of deformation declines considerably but not enough.
- 3. A further addition of paraffinic acid produces a sharp decline of the solidity of the vulcanized material. The degree of deformation remains normal.
- 3. The second test series investigated the treatment of aluminum oxide with agents to improve the mixing properties of the filling agent with rubber. These tests were based on the following procedure:

Solutions of various concentrations of the test material are prepared. Mater, methanol, henzoland xylol are used as solvents. Aluminum oxide is poured into the solution and stirred for 2 to 3 hours. The solution is then filtered and dried at a temperature of 70 to 105°C (depending on the boiling point of the solvent). After this process the aluminum oxide is ready for use.

The test results are listed in the following charts:

9. Conclusions of Abovelisted Tests

- a. The processing of aluminum oxide with various agents diminishes friction between rubber particles and the oxide surface produces a filling agent giving rubber a high rate of solidity (280-300 kg/cm²), and tensile strength (600-750 percent) and, simultaneously, reduces the degree of deformation (from 200,000 up to normal values).
- b. All tested materials can be divided into three groups.
- (1) The first group of admixtures lowers both the deformation degree and the solidity of vulcanized matters. This group is comprised of emulgator E-1000 and sapel.
- (2) The second group of admixtures lowers the defo degree but retains the tensile strength. This group is comprised of mersolates and paraffinic acids.
- (3) The third group of admixtures lowers the defo degree at the same time increasing moderately or strongly the solidity. This group is comprised of seral, iron-naphtate, sodium-resinate, etc.

- c. It is characteristic of all three groups that they lower the defo-degree to normal figures and considerably increase the ductility sometimes up to 1,100 percent (see tests with benzol-sulfonic acid).
- d. The use of all these admixtures usually reduces the elasticity. However, he thous have been found to belve this problem also, either by adding smaller quantities of aluminum oxide to the rubber compound or by using special agents for retaining the elasticity (see table 6).
- 10. a. This research is important because it proves aluminum oxide to be a high quality filling agent for rubber compounds and also helped to considerably simplify production methods and find a furnace design for aluminum oxide production. Aluminum oxide was produced in a test cupola furnace with exterior heating in the Buna Plant. This kind of furnace cannot be considered a model type of an industrial furnace. Auffle-furnaces used for aluminum oxide production in Wolfen and Eitterfeld are also not model furnace types if the volume of aluminum oxide and the importance of this valuable filling agent for future production is considered.

At present perfect furnace types are the modern drum rotary furnaces with exterior end interior heating and cupola furnaces with interior heating. The furnaces have a high production capacity and can be operated continuously.

- b. A rotary experimental furnace for aluminum oxide production was tested in the Polysius Plant in Dessau in June 1948. The furnace was 8 meters long and 30 to 40 cm in diameter. Aluminum sulphate was introduced at one end of the drum while the burner head was arranged at the other end. The test showed that the whole active part escaped in the smoke due to the great volatility of aluminum oxide. The part of aluminum oxide which reached the opposite end of the furnace was nonactive. This installation was not usable as separation of a volatile material such as aluminum oxide in gases heated to 1,000°C is very difficult and requires a very complicated plant with various systems of cyclone filters, etc.
- c. Cupola furnaces with interior heating obviously have the same defects. Dr. Moll proposed a noteworthy furnace construction for our aluminum oxide production department. He suggested the insertion of a thermax pipe of small diameter into a conventional rotary furnace. The heating gases cover the outside of the thermax pipe with aluminum sulphate and aluminum oxide inside, while pipe and furnace revolve. However, such a furnace cannot be regarded as a model type as there is a critical shortage of thermax material. The solidity of thermac also rapidly declines at temperatures of 1.000 to 2.000°C.
- d. The tests proved normal rotary furnaces without thermax or cupola furnaces with interior heating as the most suitable types for the aluminum oxide production. The aluminum oxide is separated from the heating gases by wetting with water or a mild soda solution or other liquids. Experiments of this kind are presently done by Engineer Khycheyan and Dr. Henn.
