**China: Implications
of Chemical Industry
Development** [redacted]

25X1

Summary

*Information available
as of 29 July 1983
was used in this report.*

China has invested heavily in the chemical industry over the past two decades in an effort to reduce dependence on imports, support industrial development, and earn foreign exchange from increased exports. From 1971 to 1980, Beijing poured nearly 12 percent of domestic capital investment and \$5 billion in imported plants and equipment into the chemical industry. [redacted]

25X1

China's reliance on imported chemicals continues to be substantial, however, with total value of imports dropping in 1981-82 only because of depressed world prices. Although China has expanded production capacity, consumption still exceeds domestic supplies. As a result, we expect China will continue to rely heavily on foreign suppliers for the foreseeable future, particularly for agricultural chemicals, plastics, rubber, and organic chemicals. [redacted]

25X1

Plans to increase exports have been successful, but such traditional products as resins, medications, and coal tar compounds still dominate Chinese sales abroad. Beijing's expectations for entering international markets as a volume seller of modern chemicals, such as petrochemical products, also have been set back by rising domestic consumption. China has begun to market chemical products more aggressively, but we do not believe it will significantly increase its 1-percent share of world chemical exports. Sales of low-priced Chinese chemicals will provoke such problems as recent antidumping actions by the United States and Europe, but we believe these problems will not be common or predictable. [redacted]

25X1

Energy availability and efficiency will continue to worry chemical industry officials. During the 1980s, chemicals will be the largest industrial consumer of energy resources, in spite of efficiency drives aimed at closing wasteful chemical factories. Petrochemical production will be a high priority, and, unless new oil resources are found, Beijing will have to divert oil from exports—now about 400,000 barrels per day—to supply petrochemical plants. China plans to increase production of chemicals from coal to complement the oil- and gas-based chemical sector, but these plans will not affect the chemical industry until the late 1980s or early 1990s. [redacted]

25X1

Secret

25X1

We expect US firms to benefit from the development of China's chemical industry through both commodity trade and technology transfer. Agricultural chemicals and plastics will continue to dominate US exports to China, with the Chinese market giving a much-needed boost to the depressed US phosphate industry in particular. Beijing also wants US technology and equipment to build or upgrade a variety of chemical plants and to improve the industry's energy efficiency. 

25X1

China's exports of chemicals are such a small share of world trade that, even if exports increased substantially, it is unlikely that Chinese chemicals would cost US firms any significant sales in third-country markets. However, we do expect US firms will suffer reductions in exports to China of urea fertilizer by mid-decade. Exports of some plastics also may level off and possibly decline by the late 1980s if China's own capacity potential is realized.

China: Implications of Chemical Industry Development ¹

25X1

For 20 years Chinese policy for expanding the chemical industry has focused primarily on two problems—meeting the needs of China's huge agricultural sector for fertilizer and agricultural chemicals and developing a domestic petrochemical industry that could provide the array of products used in all industrialized states. The past weakness of the chemical industry had led to a costly dependence upon imports. The discovery of new oil and gas resources in the early 1960s allowed Beijing to embark on a program of constructing large complexes to produce badly needed fertilizers and petrochemical products. At that time, Chinese planners, overestimating the potential impact of new capacity, also began to believe China might develop new export capabilities.

While expanded exports and reduced imports remain the primary motives, the domestic demand created by China's recent economic growth has given further impetus to chemical expansion. Technological advances in industry have created requirements for new or increased supplies of such chemical products as intermediate materials, solvents, lubricants, and plastic or rubber parts. Advances in chemical processing technologies that permit more efficient production also place continuing pressure on the chemical industry to expand and modernize. This paper examines the development of the industry in recent years and assesses the problems Beijing faces in meeting domestic needs and the prospects for a larger Chinese share of the international chemicals market.

The Chemical Industry's Role in the Economy

The chemical industry is China's third-largest industrial sector after machine building and textiles. Chemical production accounted for about one-eighth

Table 2
China: Capital Productivity, 1981

Building materials	564.8
Forestry	551.1
Food	3,186.4
Textiles	3,245.5

25X1

25X1

of gross industrial output value (GVIO) in 1981, nearly double the 1957 share. Massive infusions of foreign technology and equipment in the mid-1960s and again in the 1970s contributed to rapid increases in output value (see table 1).

25X1

Among the 10 major industrial sectors, the chemical industry is second only to textiles as a direct source of economic growth (measured in terms of incremental GVIO). Chemical output yielded about 16 percent of the increase in GVIO between 1977 and 1981. Chemicals also support growth indirectly, providing major inputs to the important agricultural sector and raw materials for other products.

25X1

25X1

The chemical industry's capital productivity is high, ranking third behind the textile and food industries (see table 2). Imported technologies contribute greatly to capital intensity in chemical production—imported

1981	34.1	3.1	9.1

^a Chinese statistics available for state-owned enterprises only.

ammonia plants, for example, produce more than 4,000 tons per worker yearly, about 19 times the output per worker at Chinese-designed plants. Higher capital intensity has also permitted the chemical industry to enlarge its share of production with a declining share of the labor force (see table 3). Labor productivity in state-owned chemical enterprises increased at an average annual rate of 5.8 percent between 1978 and 1981, nearly three times the national average for industry.

Investment Trends

Between 1953 and 1981, Beijing directed an average of 10.5 percent of total industrial investment into the chemical industry; modernization drives in 1963-66 and 1973-78 boosted expenditures even higher (see table 4). These efforts were directed at developing modern, large-scale agricultural and organic chemical industries.² Beijing invested heavily in fertilizer plants and petrochemical complexes in particular—including imports of whole factories—to reduce dependence on commodity imports and to advance China's ability to produce synthetic fibers, plastics, and rubber. By 1981 agricultural chemicals, organics, plastics, and rubber products were the largest of the chemical

² Appendix A provides a more detailed discussion of sectoral development.

Table 4
China: Investment in the Chemical Industry ^a

Year	Total Investment in Industry (billion yuan)	Investment in the Chemical Industry (billion yuan)	Chemical's Share of the Total (percent)
1953-57	25.0	1.4	5.6
1958-62	72.8	5.5	7.6
1963-65	21.0	2.4	11.4
1966-70	54.2	6.2	11.4

1978	27.3	3.1	11.4
1979	25.7	2.9	11.3
1980	27.4	3.0	10.9
1981	21.5	1.9	8.8
1981-85 (Plan)	120.2	11.4	9.5

^a Chinese statistics are available only for state-level capital construction investment. Additional expenditures are made by localities and factories but are not enumerated in published data and, therefore, are not included in these tables.

industry's eight sectors (see figure 1). Now that many of the major processing projects are under way, Beijing is placing greater emphasis upon downstream processes, notably plastic for consumer products. At the same time, investment in the inorganic chemical industry also appears to be increasing (see table 5). Table 6 displays output data for several products, illustrating the impact of China's chemical industry investment.

Investment in chemicals in 1981-85 will drop to 9.5 percent of total industrial investment, according to the Sixth Five-Year Plan. This is because the completion or near-completion of large-scale raw materials processing complexes will allow China to shift investment to downstream chemical plants that are less costly.

Plant Imports Enhance Expansion

Western plants and equipment have been the underpinnings of China's effort to develop a modern chemical industry. Chemical plants—almost exclusively for petrochemicals and fertilizers—accounted for nearly half the value of plant import contracts signed in 1963-79 (see table 7 and figure 2). [Redacted]

Although China has the capability to build some types of chemical plants, imported facilities are the sole producers of some products and primary producers of many. We estimate, for example, that nearly all of China's ethylene is produced in imported plants or in Chinese-designed plants that use imported equipment; imported urea plants by 1980 produced one-fourth of China's nitrogen fertilizer and 80 percent of its urea. [Redacted]

1979	87	1,066	8.2

Figure 2
China: Share of Total Plant Imports Held by Chemical Plants

Chinese-designed plants predominantly produce inorganic chemicals and low-grade fertilizers. In general, the technologies are outmoded by Western standards; nevertheless, they are suited to small-scale production for local use. Without imported plants, we estimate that China's capacity to produce ethylene would be less than 5 percent of current levels; plastics, 15 percent; synthetic fibers (excluding cellulosic), 20 percent; and nitrogen fertilizer, 75 percent.

Infrastructure Problems

Energy

The chemical industry is the largest industrial consumer of energy resources, drawing 17 percent of 1981 electricity output in addition to the oil, gas, naphtha, and coal used as feedstocks. Government concern about energy availability has forced the chemical industry to plan expansion more carefully and to restructure operations for increased efficiency. For example, construction of several fertilizer and petrochemical projects purchased in 1978 was delayed largely to assure availability of energy feedstocks, although financing, demand, location, and transportation factors also were reviewed.

Energy conservation promises to be a continuing pursuit. Under the economic readjustment policies of the past few years, officials specifically sought to close small plants, which produce a variety of goods for local consumption, because of inefficient operations. Many chemical plants were included, especially the almost 2,000 local fertilizer producers. Small, ammonia-based nitrogen fertilizer plants are the most intensive and inefficient energy consumers in the chemical industry. We estimate that in 1978 these plants alone used 4.5 percent of China's electricity supply and accounted for 2.6 percent of total energy consumption. By 1981 nearly one-fourth of these 2,000 plants were closed, electricity use was down to 3.7 percent and energy use to 3.1 percent. Nevertheless, in 1981 the nitrogen fertilizer industry as a whole still consumed 4.5 percent of energy supplies to produce less than 2 percent of GVIO.

25X1

25X1

25X1

25X1

25X1

Secret

During a January 1983 industry meeting, the Chemical Ministry launched a new efficiency drive aimed at closing as many as 400 mainly smaller plants by 1985 if they cannot increase quality and reduce energy consumption. We estimate that planned 1985 output levels for nitrogen fertilizer alone will require 4.3 percent of projected primary energy production. [redacted]

Petroleum Feedstock Prospects

China's large-scale petrochemical complexes run on crude oil supplied primarily by the Daqing and Shengli oilfields. Shengli's output is declining, putting more of a burden on Daqing where officials also expect output to diminish in the late 1980s. At the same time, demand for feedstocks will increase at least 25 percent when facilities now under construction come on stream. We believe China will reduce Daqing exports—currently around 10 million metric tons yearly—if necessary to maintain supplies, rather than cut back petrochemical production. [redacted]

Some planners in Guangdong Province and the Shenzhen Special Economic Zone near Hong Kong also are considering constructing additional facilities in southern China in the late 1980s that may increase requirements by an additional 30 percent or more [redacted]

[redacted]

[redacted] Any all-new complexes would depend on offshore oil supplies and probably will not be built if supplies are not assured. [redacted]

Transportation

Inadequate rail and water transport facilities delay deliveries, which can cause deterioration of some chemical products. Some factories have built costly pipelines to assure steady feedstock supplies. But where raw materials are distant from final consumers—the Qinghai potassium beds in western China relative to eastern agricultural areas, for example—rail transport is crucial and delays delivery up to six months. Sloppy handling in transit adds to the problem; *China Daily* reports that 8 percent of yearly chemical fertilizer output is wasted by bags breaking during shipment. [redacted]

**Table 8
China: 1985 Production Plans**

25X1

Chemicals in the Sixth Five-Year Plan

The Sixth Five-Year Plan's goals for expanding chemical production are likely to be met easily. Of those products for which specific levels are enumerated, we believe only chemical fertilizers will not meet the target. Sufficient capacity already is under construction to fulfill plan requirements for ethylene, plastics, synthetic rubber, and chemical fibers. Sulfuric acid and caustic soda are already at 1985 levels, and soda ash capacity can be added easily (see table 8). [redacted]

25X1
25X1
25X1
25X1

Chemical Fertilizers

Sufficient nitrogen fertilizer capacity will be added to meet the 1985 target, but slow expansion of other fertilizers means that additional nitrogen production will impede China's efforts to balance its product mix (see appendix A). Phosphate output may approach the 1985 goal only if existing plants are run more efficiently or small plants are added; planned large-scale

25X1

Secret

projects will not be completed before 1986. Similarly, the large Qinghai potassium project will not be operational before the end of the plan period, so potassium increases will have to come from smaller projects. We do not expect the additional output from the small plants to contribute enough to reach the plan's objectives. [redacted]

Petrochemicals

Beijing reorganized the petrochemical industry this year to streamline operations and management. The China Petrochemical Corporation falls directly under the State Council and oversees more than 50 refineries and petrochemical complexes, and almost all research, trade, and planning. The corporate form was chosen to remedy the bureaucratic confusion caused by past involvement of the Ministries of Chemicals, Petroleum, and Textiles in the management of chemical facilities. [redacted]

Coal Chemicals

China plans to develop a coal chemical sector to supplement the oil- and gas-fed industry. It plans to develop a major chemical industry in Shanxi Province using abundant local coal. A large nitrophosphate fertilizer plant there will be the first of several coal chemical plants that will include calcium carbide and other carbide products. A second coal chemical facility will be in Shenyang in northeast China, where officials plan to produce benzene, naphthalene, tar, and acids. We believe coal chemicals will not be a significant factor in chemical production until the late 1980s or early 1990s. [redacted]

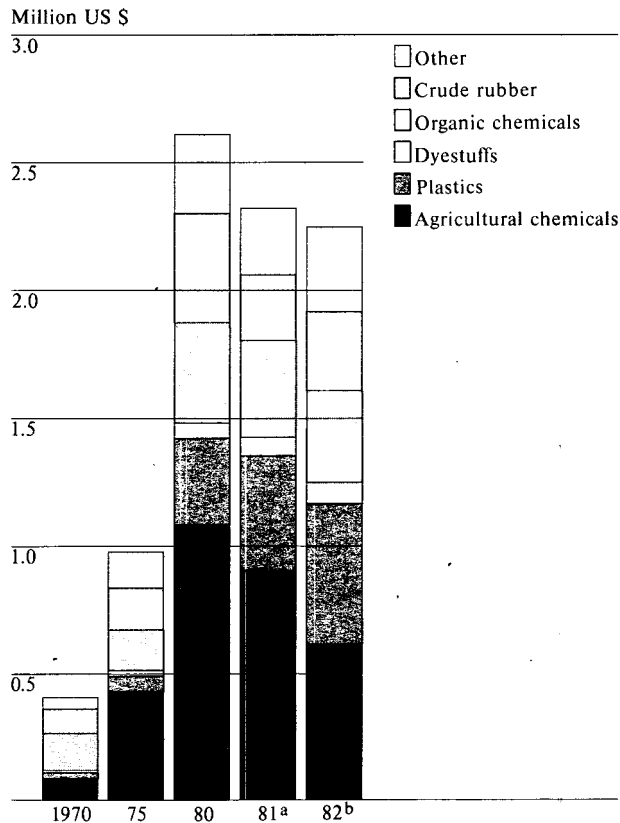

Chemical Trade

Imports Reflect Development Priorities

China buys about 1.6 percent of world exports of chemicals. Agricultural chemicals, plastics, crude rubber (synthetic and natural), and organic chemicals dominate China's chemical imports, with textile dyes a small but growing factor (see figure 3). Chemicals and rubber have accounted for 13 to 14 percent (\$2.2-2.6 billion) of the value of all imports in each of the last three years. [redacted]

Agricultural chemicals—mostly nitrogen fertilizers—account for the largest share of chemical imports.

Figure 3
China: Major Chemical Imports

^a Lower import value in 1981-82 reflects depressed world prices, not reduced volume.

^b Estimate.

300434 9-83

Depressed fertilizer prices in 1982 held down total value, although volume of imports continued to rise. Imports of potassium, phosphate, and compound (multinutrient) fertilizer products are also beginning to increase. Reports from the Spring 1983 Trade Fair in Guangzhou suggest that purchases of pesticides and the intermediate chemicals used to manufacture pesticides are up sharply this year after a decline in 1982.

Secret

6

Secret

Plastics purchases have jumped 150 percent—twenty-fold in value—between 1970 and 1982 and vie with agricultural chemicals as the leading chemical import. Rubber imports fell off in 1981, largely the result of reductions in tire production, but recovered somewhat in 1982. The organic chemical category covers a broad range of products. Some of the more notable imports are ethylene glycol and terephthalic acid (both used in the manufacture of polyester) and phthalic anhydride (used in the manufacture of plastics, polyester, and insecticides). Official Chinese trade data for 1982 also show increased interest in inorganics after a lull in 1981. Purchases of soda ash increased 150 percent and of caustic soda nearly 700 percent (in volume) last year. These two products have a myriad of uses in manufacturing other products and the large volume of 1982 imports cannot be attributed to any particular activity. [redacted]

For many products, Beijing's hopes to reduce imports by adding capacity have been frustrated by rapidly expanding consumption. For example, in 1973 China purchased 13 urea fertilizer complexes capable of producing almost 6.8 million metric tons annually, more than enough to cover that year's imports (2.5 million tons) plus expected increases in consumption. By 1980 these plants on the average were operating at 70 percent of capacity, producing about 4.8 million tons—nearly double the 1973 import level. However, small plant closures in 1978-80 cut national capacity by as much as 1.5 million metric tons and consumption levels nearly tripled between 1973 and 1980, so that 1980 import requirements still exceeded 2 million tons. Beijing recognizes that imports will be a long-term necessity and is adding dockside bagging centers to take advantage of lower prices on bulk cargoes. New bagging facilities are already operating in three ports. [redacted]

According to recent press reports, the completion of the new Kunming plant will end China's dependence on imports of sodium tripolyphosphate (raw material for synthetic detergent). Imports now cost about \$60 million annually. Import substitution targets may also be met for ethylene glycol. Imports dropped substantially during 1982, probably because of temporarily reduced production of polyester. If polyester output rises in 1983, ethylene glycol imports may also increase. [redacted]

Major Suppliers. Japan, the United States, West Germany, and Italy are China's largest volume suppliers. Japan has increased exports to China steadily over the last 10 years, but its share of sales has dropped from 70 percent in 1972 to 25 percent in 1982. US sales became significant in the late 1970s, and in 1982 accounted for another 25 percent, exceeding the value of Japanese exports for the first time. [redacted]

China seems to acquire some chemical products almost exclusively from certain suppliers. France is virtually the only supplier of activated carbons; the United States, antiknock preparations for fuels. Canada is the major source of potassium fertilizers, the United States of phosphates, and Japan of nitrogen fertilizer and pesticides. [redacted]

The Soviet Union and Eastern Europe have increased their share of Chinese imports in recent years. Bloc-produced fertilizers marketed through European firms have kept world prices low and attracted Chinese buyers. The 1983 Sino-Soviet trade agreement pledged shipments of Soviet fertilizer to China but did not specify the volume. [redacted]

[redacted] we estimate the Soviets may be able to supply up to 0.5 million tons yearly, about one-fourth of China's annual nitrogen fertilizer purchases. Most Sino-Soviet chemical trade to date has been through intermediaries, but Moscow plans a chemical exhibit in Beijing for September 1983, with hopes of expanding direct trade. [redacted]

Exports: Less Concentrated Than Imports

China is a minor exporter of chemicals, accounting for less than 1 percent of the world market. Exports of chemicals reached \$1.2 billion in 1982 (exclusive of explosives³), about 6 percent of China's total sales abroad and equivalent to about half of the cost of

³ Explosives are included in the Standard International Trade Classification (SITC) chemical category, but the Chinese do not consider them a chemical, and they are not included here. However, exports of explosives—specifically fireworks—have jumped from less than \$5 million in 1970 to more than \$90 million last year, an annual increase of 28 percent. The United States is China's largest customer. [redacted]

Secret

Secret

chemical imports. Export products are more varied than imports, with the 10 highest valued categories accounting for less than half the total. Exports are dominated by natural products and intermediate chemicals made from natural products. Rosin and resin acids is the top income-producing export, with \$114 million in sales in 1981, or 9.4 percent of chemical exports. Medications, coal tar oils, heterocyclic compounds, and scents and flavors also figure prominently. [redacted]

China's customers also are more diverse than its suppliers. In 1982 Hong Kong and Japan were by far the largest buyers, each with only about 15 percent of total exports. The United States accounted for about 11 percent and West Germany, 7 percent. China also exports to other OECD nations, Soviet Bloc countries, a number of lesser developed countries, and newly industrializing countries. [redacted]

China plans to expand chemical exports and has begun to market chemical products more aggressively. Some Western manufacturers are concerned that China may be developing specific export capabilities, particularly for petrochemicals, that would undercut the sales of Japanese, North American, and European firms. [redacted]

We do not believe China is deliberately developing export capabilities to unsettle world markets, nor do we believe they are capable of doing so in this decade. Expansion, especially of petrochemical capacity, probably will not even meet growing domestic requirements for fibers, plastics, and intermediates for manufacturing. Antidumping actions over sales of menthol, potassium permanganate, and chloropicrin to the United States and barium chloride, oxalic acid, and paracetamol to Europe are likely to recur. However, we believe they will not be common or predictable. With the expansion of chemical capacity under way in the Middle East and other locations, China is not likely to significantly increase its share of world production of most chemicals. [redacted]

Quality control problems also restrain China's impact on world chemical markets. Most export products are carefully screened for quality assurance, but China has tried to sell below-par goods. [redacted]

US Ties to the Chemical Industry

We expect US firms to benefit from the development of China's chemical industry in this decade through both commodity trade and technology transfer. We believe China's consumption of such major commodities as agricultural chemicals, resins, and plastics will outpace increases in production, so import requirements will remain strong. Imports of US chemicals in 1982 amounted to nearly \$500 million, 25 percent of China's chemical imports but only 1.5 percent of US chemical exports. Agricultural chemicals, plastics, and chemical catalysts account for 90 percent of US chemical sales to China. [redacted]

The US phosphate industry—depressed since 1980 and facing further downturns because of low domestic demand—will be a major beneficiary of China's imports. At present, the United States supplies perhaps 80 percent of China's imports of phosphate fertilizers. [redacted]

[redacted] We expect China to remain the largest customer for US phosphates. [redacted]

Technology Transfer Prospects

Expansion of production capacity also will offer opportunities for US involvement. Beijing plans to build at least two phosphate plants based on US technologies [redacted]

[redacted] At least one US firm is also involved in the current construction of three new urea fertilizer plants; although built by Japanese and German companies, the plants use Texaco technology. [redacted]

25X1

China also has explored the feasibility of buying US equipment and technology to produce pesticides, polyvinyl chloride, chlorine, caustic soda, and sulfuric acid. [redacted]

25X1

25X1

25X1

Several Chinese plants have begun joint ventures with US firms to manufacture chemical products for both domestic and export markets. So far these ventures have focused on daily-use articles and pharmaceuticals, including cosmetics, deodorants, and analgesics. [redacted]

25X1

Potential Losses

China's exports of chemicals are such a small share of world trade that, even if exports increased substantially, it is unlikely that Chinese products will cause significant competition for US firms in third-country markets. We do expect US exports to China of selected commodities, however, to decline during the 1980s. Chinese imports of US urea fertilizer (sales of which amounted to \$55 million in 1982) may decline with increasing production and the availability of less costly products from Soviet Bloc and Middle Eastern suppliers. Increases in exports of some plastics (polyethylene and polypropylene, with sales of \$213 million in 1982) will probably slow toward mid-decade. If China's own capacity potential is realized, US exports of plastics may level off or even decline in the late 1980s. No other products with a significant share of China's chemical imports are likely to experience major reductions. [redacted]

Appendix A

Sectoral Development

Products for Agriculture

The chemical industry provides continuing large-scale support to agriculture. In addition to chemical fertilizers, demand for such products as herbicides, pesticides, and plastic sheet (for mulching) has increased greatly. [redacted]

China is the world's largest buyer of fertilizers, with *nitrogen fertilizer* dominating imports. Industry expansion in the 1960s entailed construction of Chinese-designed, low-grade nitrogen fertilizer plants intended to at least partially supplant import requirements. In spite of increased production, however, imports continued to rise—doubling from 1965 to 1967. Finally, in the early 1970s, policymakers decided to import 13 modern urea (high-grade nitrogen) plants. As those plants became operational, China's reliance on imports, [redacted]

[redacted] dropped to 14 percent of supply in 1980 from more than 24 percent in the early 1970s, and it appeared that the import substitution policy was succeeding. Three additional plants are now under construction, but imports are running higher than ever (in volume terms), back up to 16 percent of supply [redacted]

Beijing's long-term preoccupation with nitrogen has left *phosphate and potassium fertilizer* capacity underdeveloped. Without appropriate proportions among these three nutrients, fertilizer applications yield less than optimum results. Chinese media report government anxiety about continuing imbalances. Phosphate, potassium, and compound (multinutrient) fertilizer imports have risen sharply. An Irish firm recently completed a feasibility study for a potassium project in Qinghai Province that eventually may obviate the need for imports. One compound nitro-phosphate plant is under construction in Shanxi Province, and a second, imported from Romania, is being built in Anhui. China has large phosphate reserves, but they are inaccessible and, because of impurities, hard to process. Until an effective method is available to exploit domestic resources, officials expect to remain dependent on imports of phosphate rock or

phosphoric acid for inputs to fertilizer plants or on imports of finished phosphate fertilizers. [redacted]

25X1

China balances use of *crop-protection chemicals* (insecticides, herbicides, and fungicides) with natural agents. A visiting scientific delegation in 1975 lauded Chinese nonchemical insect controls after observing hundreds of ducks herded through a rice paddy, eating, according to the group's host, about 200 insects per hour per duck. China, however, wants to develop a modern, varied pesticide industry to supplement such biological pest controls. [redacted]

25X1

25X1

[redacted] DDT and benzene hexachloride (BHC; lindane) were the primary pesticides in use through 1982. However, research on retention of organochlorine pesticide residues in humans led to the issuance in mid-1982 of new health standards and safety regulations for pesticide use, and now Beijing has ordered a halt in production of DDT and BHC by 1985. In spite of highly publicized concern for pesticide safety, the principal alternatives to DDT and BHC are organophosphorous agents, most of which are highly toxic; one safe new product (phoxim) that impressed the 1975 delegation apparently is not yet widely available. [redacted]

25X1

25X1

25X1

25X1

25X1

The pesticide industry seems to be in disarray. Many factories have been closed or reorganized, first by the readjustment and more recently by the ban on the two major products. Raw materials shortages have reduced operations at some remaining plants. All told, annual production has slipped back to the 1977 level, 15 percent below peak output in 1979-80. Demand has fallen as well. Under the new agricultural incentive program, farmers themselves must buy pesticides that formerly the state distributed, and apparently many believe these pesticides are ineffective and are balking at paying the asking price. In June 1983, Beijing announced plans to build 20 new pesticide

Secret

Secret

plants by 1985 with total capacity of 20,000 tons, about a 4-percent addition to current production levels. [redacted]

Planned use of *plastic sheets* for mulching will quadruple in 1981-83 but will still cover less than 1 percent of sown area. *Zhongguo Nongmin Bao* reports that yields of cotton and peanuts from mulched fields increased 30 to 70 percent compared with yields from unmulched fields. The Ministry of Agriculture, encouraged by these results, is now urging more widespread use of plastic mulch and has asked the petrochemical corporations to increase production. [redacted]

Products for the Textile Industry ⁴

In the early 1970s, Beijing decided to develop a major petrochemical-based *synthetic-fiber* sector, with major new production facilities in Shanghai, Tianjin, Liaoyang, Daqing, Nanjing, and Beijing. By 1979 China had signed nearly \$3 billion in contracts for plants to produce textile-grade synthetic fibers and associated products. The Textile Ministry publicly gave priority to the chemical-fiber sector in 1980, with 80 percent of state investment for the textile industry allocated to chemical fibers. Some of these facilities are under Textile Ministry jurisdiction but are included here since they affect overall chemical industry production. [redacted]

China, once reliant on natural fibers, now produces rayon, acetate (cellulosic fibers), nylon, acrylic, and polyester (the noncellulosics). Manmade fibers accounted for 14 percent of fiber production in 1980 and could reach 24 percent by 1985. Their availability has spurred a near revolution in the textile industry, where they have contributed to improved supplies of apparel for both domestic and export markets. [redacted]

Synthetic fibers are contributing to other industries as well. Polypropylene is replacing cloth and burlap for shipping bags, for example. Industrial-grade synthetics also serve as tire cord, conveyor belts, tubing, hoses, and other purposes. [redacted]

Dyes and fabric finishes have not kept pace with textile production capabilities. China has been unable to produce colorfast dyes and other chemical treatments in the quantities and quality needed. It also has been slow to develop and distribute processes for mildew prevention, water and soil repellency, and other such features, concentrating available capacity on export goods instead. Beijing has purchased additional capacity to produce dyestuffs in an effort to upgrade that industry and is slowly expanding other chemical treatment capabilities. [redacted]

Products for Other Industries

China's *plastics* industry is expanding in conjunction with synthetic fibers since they are, for the most part, coproducts of petrochemical processing. Plastics production originated on a small scale in the 1950s, but received little attention until the 1960s. Imports, mostly of polyvinyl chloride, skyrocketed in 1967 even as new, imported capacity was under construction. In spite of the additions to capacity throughout the 1970s, imports have increased steadily. By 1980, according to the State Statistical Bureau, imports of PVC and polyethylene reached 120,000 tons, nearly 12 percent of supply. [redacted]

China's plastics production reached 1 million tons last year, primarily PVC, polystyrene, polypropylene, and high- and low-density polyethylene. The products are manufactured into film and sheet (for packaging, utility, and agricultural use), containers, hose, pipe, cable, and wire insulation; rainwear, shoes, and other consumer goods; and moldings and extrusions such as radio cases. At least one Shanghai plant produces polyvinyl carbazole expressly for electronic components that require high temperature resistance. An imported synthetic leather plant nearly complete in Shandong Province has a design capacity of 3 million square meters, enough to increase the production of leather shoes by 20 percent. [redacted]

Beijing plans continued development of the plastics industry. Last year, China acquired polystyrene technology from Japan for a new 5,000-ton plant in Lanzhou to manufacture housings and parts for televisions and other electrical goods, beginning in 1984.

Secret

Secret

Currently in demand is Western equipment to upgrade injection molding capabilities and to produce plastic products for consumption such as trash bags, toys, and household containers. [redacted]

China also has issued inquiries to increase methyl methacrylate capacity (now less than 12,000 tons) concurrent with acrylonitrile fiber expansion (a by-product of acrylonitrile production is used to manufacture methyl methacrylate). Methyl methacrylate applications cover the full range of uses for clear plastics, from display cases to aircraft windows and protective coatings. [redacted]

China is the world's fifth-largest producer of *natural rubber* (150,000 tons in 1982) and supplements that with *synthetic rubber* (123,000 tons). Domestic production furnishes about half of supply, the balance being natural rubber from Southeast Asia and Sri Lanka and synthetic rubber from the West. The Chinese Academy of Sciences claims discovery of a new catalyst that could double synthetic rubber production, and Agriculture Vice Minister He Kang says China also wants to double production of natural rubber. He Kang expects natural rubber imports to expand, in any case. [redacted]

The two largest consumer products of rubber in China are rubber shoes (including sport shoes) and tires. Rubber footwear output has increased about 3.5 percent annually since 1958 and has become a \$45 million export industry. China and Nike have established a joint venture to produce Nike sport shoes but have had trouble getting the project into production. Tire output dropped sharply in 1981 following the contraction of wheeled vehicle production, but is still the primary rubber product industry. To improve tire quality, China has put an imported nylon tire cord plant into production and wants Western help to manufacture radials. Dunlop (UK) is providing the equipment and know-how to manufacture 130,000 truck tires, half for export, and is discussing additional projects to produce tires, hydraulic hoses, and latex foam. [redacted]

Synthetic detergents have undergone considerable growth with the addition of alkylbenzene plants in Nanjing, Liaoyang, and Beijing and a sodium tripolyphosphate plant in Kunming. *Jingji Guanli* in 1982 revealed that China's per capita detergent output was less than 10 percent of the world average and urged continued expansion. The journal listed synthetic detergents as one product that China will not be exporting for many years. *Toiletries and cosmetics* is one popular sector of the chemical industry that will see expanded exports. China has added capacity for a variety of personal products, including deodorant and plastic razors. Many of these projects are joint ventures with foreign firms with output destined for both domestic use and exports. [redacted]
