TITLE: Polymerization of Ethylene Under the Influence of γ -Radiation 19

PERIODICAL: Vysokomolekulyarnyye sovedineniya, 1960, Vol. 2, No. 6,
pp. 904-915

TEXT: The radiation-chemical polymerization of ethylene in the gaseous phase and in organic substances was investigated at different pressure and radiation dose as well as some properties of the polymers formed.

Co^{60} γ -radiation sources of the institut im. Karpova (Institute imeni Karpov) (1400, 1800, and 20000 gram equiv. Ra) and pressures of 50-300 atm, radiation dose of 17 to 165 r/sec, and 25°C (some experiments were made at 50°C) were the conditions. The experiments were carried out in a corresponding device (Fig. 1). The ethylene used was mass-

ABKIN, A. D.

Investigation of copolymerization of hexadecyl and methyl acrylates in a toluene solution. S. N. Kamenskaya, A. D. Abkin, and S. S. Medvedev. *Doklady Akad. Nauk S.S.S.R.* 196, 855-8 (1963); *Ch. C.A.* 45, 3227c. The relative reactivity of polymerization of 2 chemically similar monomers and their copolymerization was studied on the basis of the results reported before (*loc. cit.*). Me acrylate was purified by washing, drying, and distn. at 33-9° and 1.55 mm. Hg. Ether (distd. from the monomer) was used in its polymerization, doing away with the induction period. Hexadecyl acrylate was synthesized from hexadecanol and Me acrylate in the presence of *p*-toluenesulfonic acid. The ester was distd. *in vacuo* in the presence of metallic Cu, and the 155-90° fraction at 1.4 mm. Hg, m.p. 24°, $n_D^{20} = 1.4599$, $d_4^{20} = 0.859$, was collected. Pure Br_2O_2 was used as the reaction initiator. For copolymerization, a toluene soln. with the monomer concn. of 1.5 moles/l. was used. The polymerization rate was observed dilatometrically, at 50 ± 0.05°. The hexadecyl acrylate polymerization rate was found to be 2.3 times greater than of Me acrylate, and this rate was found to be the same at lower concns. of monomers. The copolymerization rate was calcd. by using the previously derived formula, which involved the use of the individual polymerization rates of the monomers, and the coeff. λ which characterizes the ratio of the ratio of the constants of the individual monomers polymerization initiation. The value of λ was found to be 6 from the kinetic data, and nearly the same value from the av. of polymerization. By assuming the value for the Me acrylate chain growth $k_{p,MA} = 10^6 \text{ mole}^{-1} \text{ sec}^{-1}$ (Matheson, *et al.*, *C.I.* 46, 1870), the values for $k_{p,HA} = 1558$; $k_{i,HA} = 1807$; $k_{i,MA} = 1731$; and $k_{t,HA} = 1256$.

spectroscopically analyzed by M. V. Tikhomirov and M. V. Gur'yev. The molecular weight of the polyethylene obtained was determined by the method of light scattering by I. G. Soboleva and N. V. Mekletsova; particular data on this will be given in a separate paper. The experiments of polymerization in heptane, cyclohexane, methanol, and acetone (50 atm, 25°C, ~100 r/sec) showed (Table 1) that reaction proceeds ten times more rapidly than in the gaseous phase. The polymers formed have a molecular weight of 20000-40000. Polymers of the structure $\text{Cl}_3\text{C}(\text{C}_2\text{H}_4)_2\text{Cl}$ (60%) and $\text{Cl}_3\text{C}(\text{C}_2\text{H}_4)_3\text{Cl}$ (20%) form in good yield in carbon tetrachloride. Polymerization in the gaseous phase was investigated at constant pressure (100-300 atm, 72 r/sec) and decreasing pressure (100 and 150 atm, 17-165 r/sec, 25° and 50°C). The polymer yield increases rapidly if experiments are made in the presence of polyethylene (Table 2). To begin with, the polymerization rate increases with time and reaches then a constant value. The mean molecular weight and the characteristic viscosity of the polymers increases with proceeding transformation (Table 3). The mean reaction rate amounts to 16.9 g/l.hour at 300 atm, 25°C, a duration of 24 hours and radiation dose of 72 r/sec, and the maximum rate

Card 2/4

B015/B064

20.5 g/l.hour (Table 4). The mean molecular weight and viscosity of polyethylene (Table 5) rise with pressure (i.e. the ethylene concentration). The maximum rate of polymerization increases somewhat with the radiation dose with a proportionality factor of 0.3, while the radiation-chemical yield decreases with an increase in the radiation dose with a factor of 0.7. The molecular weight of polyethylene increases with a reduction of the radiation dose with a factor of 0.7. The molecular weight of polyethylene increases with decreasing radiation dose (Table 6). A temperature increase from 25°C to 50°C at constant ethylene concentration (330 g/l) causes a lesser increase in the polymerization rate and the molecular weight (Table 7). Investigations carried out by Yu. M. Malinskii and B. I. Everev in the laboratory of radiochemistry of the authors' institute showed that the polyethylene obtained has a higher density (0.945-0.975 g/cm³) and degree of crystallization than high-pressure polyethylene, differs, however, only slightly from the latter with respect to the tensile strength. In conclusion, the authors thank A. Kh. Bregor, V. B. Osipov, and V. A. Gol'din for assisting in carrying out the experiments with the gamma emitters. There are 8 figures, 7 tables, and 11 references: 5 Soviet, 4 US, 1 British, and 1 Belgian. X

AUTHOR: Abkin, A. D.

TITLE: Radiation polymerization

SOURCE: Trudy 11 Vsesoyuznogo soveshchaniya po radiatsionnoy khimii. Ed. by L. S. Polak. Moscow, Izd-vo AN SSSR, 1962, 430-449

TEXT: Results of (mostly Western) investigations in the field of radiation polymerization are reviewed. The subjects covered include radical polymerization, polymerization in a variety of systems and also in the three phases. Ionic polymerization in the liquid phase is discussed for iso-butylene, styrene, butadiene and trimethyl-2,4,4-pentene-1. Some conclusions are drawn concerning the mechanisms of the polymerization processes and equations and graphs are presented to show the relations between the various parameters. Experiments were carried out over the range +60 to -112°C. Carbanionic polymerization is also considered, in some detail, for acrylonitrile in various solvents. It was shown that radiation polymeri-

Card 1/ 3

Radiation polymerization

zation proceeded by an anionic mechanism, the rate of which in trimethylamine, over the range +25 to -112°C, fell initially to a minimum of about -50°C and then increased rapidly. Increase in the rate of polymerization was also accompanied by a significant increase in molecular weight of the polymer. Addition of styrene to solutions of acrylonitrile in dimethyl-formamide at -78°C reduced the rate of polymerization. A section is devoted to the mechanism of ionic polymerization in the liquid phase and a theory is established for the monomolecular mechanism of chain rupture in the low-temperature polymerization of iso-butylene and styrene, associated with ejection by the growing carbonium ion of a proton and the formation in the final group of the polymer chain of a double bond. An equation is given for the ratio of joint polymerization,

$$\omega = \frac{(\lambda + 1)(r_1 A^2 + 2AB + r_2 B^2) \omega_A \omega_B}{\lambda \omega_B r_1 A^2 + \chi \omega_A \omega_B AB + \omega_A r_2 B^2} \quad (1)$$

Card 2/3

Radiation polymerization

where A and B are the monomer concentrations; ω_A and ω_B are the individual rates of polymerization; λ is a quantity characterizing the ratio of the rates of formation of initial active centers from the monomers A and B by their joint polymerization; X is a quantity characterizing the ratio of the constants of the rates of 'cross' chain rupture and the rates of joint chain growth. There are 3 tables, 8 figures and 80 references.

TITLE: Radiation polymerization of vinyl chloride in solid solutions at low temperatures#

SOURCE: AN SSSR. Doklady, v. 164, no. 2, 1965, 365-367

TOPIC TAGS: vinyl chloride, radiation polymerization, mineral oil, solid solution

ABSTRACT: The polymerization of vinyl chloride was carried out in mineral oil at a dose rate of 70 rad/sec (Co⁶⁰) and temperatures of -78 and -196C, i. e., above and below the melting point of vinyl chloride. Considerable postpolymerization was found to take place during thawing of the solutions, so that the latter was carried out very rapidly when kinetic data were taken. The kinetic curves obtained show that at -196C the reaction rate decreases sharply during the first stage, and the polymerization practically ceases at 15 - 20% conversion; the yield of polymer becomes markedly reduced when the vinyl chloride content increases from 6 to 15%. At -78C, the reaction rate increases sharply at first, then reaches a maximum, and declines rapidly at 50 - 60% conversion. The products formed are low-molecular polymers. It is postulated on the basis of the kinetic data that the polymerization of vinyl chloride in a solid mineral oil solution is determined by a

Card 1/2

L 4289-66

3

definite ordered arrangement of vinyl chloride molecules. The structure of the frozen systems also affects the polymerization process. In contrast to amorphous solutions of vinyl chloride in low-molecular paraffins, the solid system vinyl chloride-mineral oil is a microheterogeneous one; in the presence of microheterogeneity, significant kinetic effects can take place. TITLE: Radiation-induced polymerization of tetrafluoroethylene and acrylonitrile at 4.2 K ¹⁹ ²⁰ ^B

SOURCE: Vysokomolekulyarnyye soyedineniya, v. 8, no. 5, 1966, 961-962

TOPIC TAGS: tetrafluoroethylene, acrylonitrile, bulk polymerization, low temperature polymerization

ABSTRACT: Polymers of tetrafluoroethylene or acrylonitrile have been prepared by bulk radiation-induced polymerization of the monomers at 4.2 K. Molten monomer samples were frozen at a given rate in liquid nitrogen, placed in a cryostat with liquid helium, and irradiated. Defrosting of the samples was conducted under conditions which excluded post-polymerization. The authors assume that in the course of polymerization of the monomers at low temperatures the bulk temperature of the samples does not determine the character of the polymer chain formation, which takes place in "hot" regions. The polymer chains grow before relaxation of the vibration excitation of molecules in "hot" regions has time to occur. The authors also assume that polymerization follows the cooperative mechanism which does not require activation for the addition of individual monomer molecules. Orig. art. has: 1 figure. [BO] 2

TITLE: Radiation polymerization of ethylene in enlarged laboratory apparatus.

SOURCE: Plasticheskiye massy*, no. 2, 1964, 3-6

TOPIC TAGS: ethylene, radiation polymerization, reactor design, reactor surface area, reaction rate, polymer yield, reactor temperature field

ABSTRACT: Radiation polymerization of ethylene was conducted in laboratory reactors of 1-2 liter capacity (fig. 1 & 2). Based on tolerances admitted in this work, it was found that the temperature field can be calculated with sufficient accuracy. Comparison of reaction rates and yield of ethylene polymer shows that these factors are independent of the specific surface of the reaction space. Thus

TITLE: Low-temperature polymerization of ethylene tetrafluoride in liquid phase by the action of gamma radiation

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 3, no. 2, 1961, 320

TEXT: In this letter to the editor the authors state that they were the first to examine the liquid phase polymerization of ethylene tetrafluoride under the action of gamma radiation. The polymerization was conducted in sealed glass phials in the absence of oxygen, at -55°C and 10 roentgen/sec. Under these conditions, the reaction took place at a high rate and was accompanied by the formation of a solid polymer. After one hour, the yield of polyethylene tetrafluoride was 35%. It was increased up to 95% by a radiation of 6 hr. The studies were continued by Ye. F. Volkova, A. V. Fokin, V. M. Belikov (Tezisy dokladov na II Vsesoyuznom soveshohanii po radiatsionnoy khimii, 1960 str. 65 (Theses of the Reports on the 2nd All-Union Conference of Radiation Chemistry, Moscow, 1960, p. 65) Ref. 1). The

publications show (S. S. Medvedev, A. D. Abkin, P. M. Khomikovskiy, G. N. Gerasimov, V. F. Gromov et al., Vysokomolek. soyed. 2, 904, 1960, Ref. 2) that ethylene under similar conditions is polymerized more slowly. This difference in the polymerization rates of ethylene tetrafluoride and ethylene may be due to a slower rupture of chains by recombination in the polymerization of ethylene tetrafluoride due to repulsive forces. The latter occur in the approximation of perfluorinated radicals of polyethylene tetrafluoride. The slow rate of chain ruptures may also be due to topochemical peculiarities occurring in the polymerization of ethylene tetrafluoride.  The structure of lactonin and gentonic acid. A. Abrikosov and B. Medvedev. J. Gen. Chem. (U. S. S. R.) 4, 1407-14 (1934). Santouin (I) dissolved in liquid NH₃ in a sealed tube at room temp. within 3 days. Evapn. of the NH₃ and purification of the residue with dry boiling PhH gave in quant. yield the amide (II) of gentonic acid, m. 162-3° (decumpon). II with hot alkali soln., alc. and H₂O readily gave I, although dry II is stable. II crystd. from CHCl₃ with 1 mol. of CH₂Cl₂ removed completely only by heating in vacuo. In the presence of moisture both NH₃ and CHCl₃ were evolved while the cryst. form was retained. It was not possible to convert II to the lactam analog of I. Actual evidence was obtained for the structure III for gentonic acid. An improved method for prep. III consists in refluxing 200 g. NaOH, with 250 cc. H₂O for 1 hr. in the absence of CO₂, then adding 50 g. of I and boiling for 12 hrs. Cooling, shaking in portions with concd. HCl, extg. with Et₂O, evapg. the Et₂O, purifying by dissolving in Na₂CO₃ soln. and repptg. with HCl, and finally recrystg. twice from 60% alc. gave colorless III, m. 162-3°, in 55% yield. III with H₂SO₄ gave a lactone (IV), which could be converted to another lactone (V). IV gave the amide (VI) with liquid NH₃. VI gave the lactam (VII) but could not be converted to VIII. III (15 g.) in 200 cc. AcOH

Kinetics of polymerization of butadiene in presence of metallic sodium. A. ABRUM and S. ANDRUSOV (J. Phys. Chem. Russ., 1939, 13, 765-718).—An earlier paper (A., 1938, 296) is amplified. Polymerization is not confined to the surface of the polymeride but proceeds throughout it. The sorption of butadiene by the polymeride has been examined at 20–40°; the order of the polymerization reaction varies with temp. between 1 and 2, corresponding with variations in the index of the sorption isotherm. The relation between the rate of polymerisation and the rate of diffusion of the monomer in the polymeride has been established, and val. of the diffusion coeff. and energy of activation have been calc.

ABK II, A

Kinetics of the polymerization of 1,3-butadiene in the presence of phenyl isopropyltinane. O. Mamontova, A. Abkin and B. M. Freid. *Acta Physicochim. U. R. S. S. R.*, 20-22 (1966). (In English). — In ether soln. the polymerization curve of 1,3-butadiene is linear with a slight deviation from Raoult's law. On addn. of butadiene to ethereal phenylisopropyltinane (I) the cherry-red color disappears; at the end of the polymerization the red color reappears. A study of the kinetics of polymerization shows that the initial active centers form on the walls by interaction of butadiene and I soln. and that chain growth then takes place in the vol. of the soln. Chain rupture occurs either unimolecularly in the soln. or on reaction with butadiene on the surface; the I is regenerated. The kinetics obeys the equation $w = k_1 C_1^2 / (1 + k_2 C_1 + k_3 C_1^2)$, where C_1 = concn. of butadiene, k_1 and k_2 are rate const. for formation and rupture and change with temp., resp., as follows: 8°, 40, 56; 15°, 36, 10; 25°, 20, 2. The apparent energy of activation of the whole process is 7.5 kcal./mol. Comparison of kinetic and chem. data shows that the polymerization is a chain-catalytic reaction. P. H. Rathmann

Kinetics of the polymerization of Δ^2 -tetrahydrocannabinol in presence of potassium thiocyanate. O. Mamontova, A. Akhan, and S. Medvedev (*J. Phys. Chem. Russ.*, 1940, 14, 32-40).—The rate of polymerization was determined from the reduction of vol. of gas over $(C_2H_5CO)_2O$ over a solution of $KSCN$ (II) in Et_2O , the pressure p of O_2 being kept const. When p increased (between 440 and 630 mm. Hg), the rate increased at first slowly, then rapidly, and then again slowly; the highest rate at 55° was about 6 c.c. of gas per min. and per c.c. of solution. The effect of the concn. of (II) (between 10^{-2} and 6×10^{-4}) was indistinct. An increase of the surface area of glass in contact with solution raised the rate but < proportionately to the area. From measurements at 5°, 15°, and 35° the activation energy was calc. to be 7000 g. cal. The reaction chains probably started at the surface, grew in the bulk of solution, and broke down both at the surface and in the bulk. Saturated solutions of (I) in Et_2O are 0.2M. and 0.72M. at $p_{O_2} = 578$ and 637 mm. Hg respectively. I, J, II

ABR 11, 1947

31

The mechanism of the simultaneous polymerization of butadiene with vinyl cyanide and *N*-methylvinyl cyanide under the action of benzoyl peroxide. L. Gordin, A. Abkin, and S. Medvedev (Karpov Inst. Phys. Chem., Moscow). *J. Phys. Chem. (U.S.S.R.)* 21, 1200-87 (1947) (in Russian).—Mists of butadiene (I) (*x* wt. %) with CH₂:CHCN (II) (100 - *x* %) or CH₂:CMeCN (III) (100 - *x* %) and (BzO)₂ (y%) were prepd. in N, heated *t* hrs., and distd. at room temp. in a high vacuum 2) hrs. The distn. residue (= polymer) was analyzed for N (i.e. nitrile) and active O (i.e. BzO). For the detn. of active O the polymer must be dissolved in CHCl₃, not in acetone. The rate *v* of formation of polymer decreases when *x* increases; e.g. at 60° for the system I + II (*y* being 0.6%) the initial rate is 0.26% per hr. at *x* = 90% and 8.3% per hr. at *x* = 20%. During one expt. *v* is almost const. at small *x* and increases with time at large *x*. The *v* increases with temp.; e.g. 42% polymer is attained at 60° within 60 hrs. and at 70° within 11 hrs. The *v* is proportional \sqrt{y} between *y* = 0.3 and *y* = 10 wt.%. These results are discussed from the viewpoint of Abkin and Medvedev, *C.A.* 24, 7710³. The polymerization ceases when one of the components is used up. The highest yield of polymer

(over 90%) is observed at *x* = 50% for the I + II and near *x* = 70% for the I + III system. The compn. of the polymer depends little on the time of polymerization and temp., but varies according to *x*. In the I + II system, the polymer contains more I than the original mixt. at *x* < 53% and less than the original mixt. at *x* > 53%. In the I + III system, the "azeotropic" mixt. has *x* = 60%. The concn. of (BzO)₂ in the polymer decreases when *t* increases. However, polymerization continues also after this concn. becomes zero. Monomer, distd. from the polymer and again mixed with it, polymerizes at the same *v* as if no distn. occurred, but soln. and repptn. of polymer remove its catalytic activity. The compn. of a copolymer depends on the constn. α and β expressing the relative rates of reaction of 2 free radicals with the 2 components of the monomeric mixt. A simple method for computing α and β from exptl. data is shown. From the values for α and β the distribution of monomer groups within the copolymer can be calcd. (cf. *C.A.* 42, 804b). In the copolymer I + II, 67% II is present as one nitrile group between 2 butadiene groups; and in I + III 80% III is in this alternate pattern. The cessation of polymerization when I of the components is used up shows that both components are needed for the branching of the reaction chain.

Kinetics and mechanism of copolymerization. A. D. Abkin (L. Ya. Kat'kov Phys.-Chem. Inst., Moscow). *Dokl. Akad. Nauk S.S.S.R.* 73, 605-6 (1950).—The rate of consumption of the sum of 2 monomers A and B can be expressed by $w = k_{11}A^2 + k_{12}A^2 + k_{21}B^2 + k_{22}B^2$, where the symbols denote the consts., and the dots designate the corresponding polymer radicals. With $R = A + B$, and the conditions of mixture (rate of initiation = rate of termination), this becomes $w = k_{11}k_{22}(k_1 + k_2)/k_t^{1/2}(a/b)$, where k_1 and k_2 = rates of initiation in sep. polymerization, k_t = rate const. of termination, and $a = k_{11}A + 2AB + k_{12}B$, and $b = k_{22}B + k_{21}A$, with $\alpha = k_{11}/k_{12}$ and $\beta = k_{22}/k_{21}$. In polymerization initiated by B_2O_2 , the factor multiplying (a/b) in the above equation becomes $1.42 (k_1'/k_2')^{1/2} \alpha(A + B)/iP^{1/2} k_{11} k_{22}$, where P = concn. of the peroxide, and $\lambda = k_1'/k_2'$ = ratio of the rate consts. of initiation for the monomers A and B, resp. With λ known, this permits calcn. of $\beta = k_{11}/k_{22}$, and hence of the rates for any binary system in relative units. If, in addition to it, the abs. value of one of the individual propagation consts., and k_t , are known, the remaining 3 propagation consts. can be calcd. from kinetic data. Such calcns. were carried out and found in agreement with literature data. At const. sum $A_0 + B_0 = C_0$, the rates of sep. polymerizations of A and of B, become, resp. $w_1 = 1.42 (k_1'/k_2')^{1/2} k_{11}^{1/2} (C_0)^{3/2}$ and $w_2 = 1.42 (k_2'/k_1')^{1/2} k_{22}^{1/2} (C_0)^{3/2}$, and the rate of copolymerization becomes $w = \lambda(A + B)^{1/2} (w_1 w_2 / C_0)^{1/2} (a/b')$, where $b' = \alpha\beta B + \lambda^{1/2} w_1 w_2 / C_0$; if the rate of initia-

tion is a quadratic function of the concns. of the monomers, the factor multiplying (a/b') is $\lambda(A + B)^{1/2} (w_1 w_2 / C_0)^{1/2}$. This equation permits calcn. of binary systems from the rates of sep. polymerizations; plots of w as a function of the proportions of A and of B, for different values of λ (from 0 to 100), constructed with the aid of this equation, were tested with satisfactory results against exptl. data for different monomer pairs. The consts. λ and β are related by $w_1/w_2 = \lambda^{1/2} \beta$. With λ and β known, the relative reactivities of different radicals can be calcd., and are found to increase in the order styrene, butadiene, methyl methacrylate, vinyl cyanide, methyl acrylate, vinyl acetate. These results lead to the following conclusions: (1) The rate of the interaction between B and A' is greater the more highly the monomer B is activated through bond delocalization, and the less stabilized the radical A'; addn. of small amts. of B reduces the total rate of polymerization sharply, and gives rise to a min. However, the rate of copolymerization can be increased through predominant initiation by one of the monomers, i.e. when $\alpha < 1$, $\beta \gg 1$. (2) Presence of a polar effect may create conditions favorable to an interaction between a moderately reactive A and a stabilized radical B', depending on β and the polar effect, addn. of B can increase the rate of copolymerization and give rise to a max. of w . Kinetics and mechanism of copolymerization of vinyl chloride and vinylidene chloride. *Izv. Akad. Nauk SSSR, Ser. Khim.* 1967, 10, 2075. (U.S. transl. in *J. Polym. Sci. Polym. Chem. Ed.* 1968, 6, 2275.)

I. Ya. Karpoz. *Phys.-Chem. Inst., Moscow. Dokl. Akad. Nauk SSSR*, 1967, 171, 1227. (U.S. transl. in *J. Polym. Sci. Polym. Chem. Ed.* 1968, 6, 2275.)

The copolymerization of vinyl chloride (I) and vinylidene chloride (II) in the presence of benzoyl peroxide (III) in an oil emulsion stabilized with Na oleate at temps. from 20 to 70° was studied in a described and illustrated vacuum app. The initial mole fractions (f_1) of I, II, and III, the reaction time (t), and the temp. (θ) were varied, the yield of copolymer and the mole fractions (F_1) of I and II in the latter are tabulated and graphed as joint functions of f_1 , f_2 , f_3 , t , and θ . For any value of f_1 , F_1 is greater than f_1 . The III is continuously consumed; when it is used up, the reaction stops. The rate of copolymerization of I and II is less than the rate of polymerization of I or II alone. II is more reactive than I, but the radical of I is more reactive than that of II.

The kinetics of copolymerization. A. D. Abkin. *Voprosy Khim. Kinetiki, Kataliza i Reaktivnosti*, *Abad. Nauk S.S.S.R.* 1955, 358-52. Copolymerization problems can be studied much more fully on the basis of kinetic data on copolymerization reactions (Abkin, *et al.*, *C.A.* 49, 45258, 50897) than merely from the quant. relations of the various polymer formations and the distribution of the monomer units in the mol. The method and results of kinetic investigation are discussed. An equation derived for the velocity of polymerization reaction gives sufficiently accurate information on the shape of the velocity-compn. curve for any real binary system and gives the value of a const. that characterizes the effectiveness of a "cross" chain rupture. Monomers with conjugated double bonds were found to be most reactive towards radicals of any type, whereas monomers with isolated double bonds are least reactive toward radicals. This is illustrated on the vinyl chloride + butadiene, vinyl chloride + vinylidene chloride, vinyl acetate + styrene, etc., polymerizations. A table was constructed of the relative reactivities of mono-

mers and radicals, and the reasons for the reactivity differences are discussed on the basis of their chem. structures.

TITLE: On the Mechanism of Copolymerization With Participation of Bifunctional Monomers (O mekhanizme sovmeatnoy polimerizatsii s uchastiyem bifunktsional'nykh monomerov). I. Copolymerization of α -Chloracrylate of 2-Ethoxyethanol With Styrene; Methylmethacrylate and Methylacrylate (I. Sovmeatnaya polimerizatsiya α -khloraakrilovogo efira 2-etoksietanola so stiroloom, metilmetakrilatom i metilakrilatom)

PERIODICAL: Zhurnal fizicheskoy khimii, 1959, Vol 33. Nr 6, pp 1387-1392 (USSR)

ABSTRACT: In connection with the problems of synthesis of branched and reticular polymers (P), investigations of the polymerization mechanism of systems with binfunctional monomers are particularly important. The copolymerization (CP) of the monomers styrene (I), methylmethacrylate (II) and methylacrylate (III) with ethylene-glycol-di- α -chloracrylate (IV) and 2-ethoxyethanol- α -chloracrylate (V) was investigated. The present paper presents the experimental results obtained with (V). The (CP) took place in methylethylketone solutions at 50°C. Benzoylperoxide was used as initiator, and the re-

Card 1/3

action kinetics was determined by the dilatometric method. On the system (III) - (V) it was observed that (V) is a more active monomer than (III) but much less active than the radical. The (CP)-constants computed for this system are $\alpha = 0.1$ and $\beta = 3.8$. A closer consideration of the reaction mechanism is put forward. In the (CP) of (II) with (V) there was computed $\alpha = 0.4$ and $\beta = 1.2$, and in contrast to the system (III) - (V), a weak maximum was observed in the diagram polymerization rate (PR) - composition (Fig 2). The latter is due to polar factors. For the system (I) - (V), the values $\alpha = 0.12$ and $\beta = 0.26$ were obtained which point to the fact that (I) is more active than (V) in the reaction with the monoester radical. In the diagram (PR) - composition (Fig 3), a distinctly marked maximum can be observed which is also produced by a polar effect. A comparison of the (CP)-constants obtained with those of the system with methyl- α -chloracrylate (Refs 8-10) (Table) shows good agreement. It is ascertained that the polymerization kinetics of the systems investigated can be well represented by the simplified equation of the

TITLE: On the Mechanism of Copolymerization With Participation of Bifunctional Monomers. II. Particularities of the Polymerization of Binary Systems With the Participation of the Ethylene Glycol Di- α -chloroacryl Ester

PERIODICAL: Zhurnal fizicheskoy khimii, 1959, Vol 33, Nr 7, pp 1495 - 1503 (USSR)

ABSTRACT: The authors investigated the copolymerization (CP) of the ethylene glycol di- α -chloroacryl ester (I) (diester) with styrene (II), methyl methacrylate (III), and methyl acrylate (IV). (I) was obtained from α -chloro acrylic acid and ethylene glycol by a method described already earlier (Ref 1). The authors checked the polymerization (P) at $50 \pm 0.05^\circ\text{C}$ in methyl-ethyl ketone at a monomer concentration of 1 mol/l. During the (P) of (I) it was found that the polymer is precipitated by (P) of 3 or 4%. For the (CP) of (IV) with (I) the (CP) constants $\alpha = 0.1$ and $\beta = 3.6$ were obtained; for the (CP) of (III) with (I), $\alpha = 0.35$ and $\beta = 1.4$, and for the (CP) of (II) with (I), $\alpha = 0.01$ and $\beta = 0.2$. Accordingly, the authors found the following: The (P)-rate of (I) is twice as great as that of the

of Bifunctional Monomers. II. Particularities of the
Polymerization of Binary Systems With the Participation of the Ethylene
Glycol Di- α -chloroacryl Ester

monoester. By the method of light dispersion it was found (Table) that ramified and reticular copolymers are formed during the (CP) of (I). In the initial stage of (CP), the reactivity of the vinyl groups of (I) is equal to the reactivity of the vinyl groups of the monoester. A characteristic feature of the (CP) of the systems (IV) + (I) and (III) + (I), i.e., with bifunctional monomers like (I), is its low separation rate, which is ascribed to the reticular structure of the resultant copolymer and regarded as a specific phenomenon of the reaction kinetics of systems with bifunctional monomers. For investigations of the particularities of the system it is assumed that the reaction acceleration with time is to be explained by an accumulation of radicals within the system, which is caused by chain transfer on the part of the polymer, or by an initiation reaction of the added vinyl groups. In conclusion, the authors thank Academician S. S. Melvedev for his assistance.

TITLE:

On the "Carbanion" Mechanism of Polymerization Under the Effect of Gamma Rays 14

PERIODICAL:

Zhurnal fizicheskoy khimii, 1959, Vol 33, Nr 11, p 2636 (USSR)

ABSTRACT:

Data from publications (Ref 1) on the polymerization of isobutylene, and data of the joint polymerization of isobutylene with vinylidene chloride and of the styrene with methyl methacrylate, obtained by the authors (Ref 2) show that at low temperatures and influenced by nuclear radiation, the polymerization occurs according to the carbonium mechanism. Up to present there is no information in publications on the course of a "carbanion" mechanism at the polymerization under the influence of nuclear radiation. It has been established that the polymerization may proceed according to both mechanisms (carbonium or "carbanion" mechanism) and that this is not determined by the chemical structure of the monomers, but by the nature of the medium. Data on the polymerization of acrylic acid nitrile and styrene at -78°C (Table) under the influence

Card 1/2

66876

SOV/76-33-11-47/47

On the "Carbanion" Mechanism of the Polymerization Under the Effect of Gamma Rays

of gamma rays, show that the polymerization of the acrylic acid nitrile in solving agents with electron donor substituents (triethyl amine, dimethyl formamide) occurs and that none occurs in ethyl chloride (which is usually used for carbonium polymerization) containing electrophilic groups. Contrary, styrene polymerizes only in ethyl chloride. These data show that acrylic acid nitrile, which has molecules containing electronegative groups, polymerizes, under the given conditions, not according to the radical mechanism, but according to the "carbanion" mechanism. It is mentioned that more detailed results of the investigations carried out will be published later and that the authors thank Academician S. S. Medvedev. There are 1 table and 3 references, 2 of which are Soviet.

TITLE:

On the Mechanism of the Low-temperature Polymerization of
Monomers Under the Action of a Gamma-radiation (O mekhanizme
nizkotemperaturnoy polimerizatsii monomerov pod deystviyem
gamma-izlucheniya)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 124, Nr 3, pp 632-634
(USSR)

ABSTRACT:

The present paper deals with the results obtained by investigating the mechanism of the low-temperature polymerization of various vinyl compounds under the action of a γ -radiation. The authors investigated this mechanism by employing the method of joint polymerization, according to which it is possible to obtain the necessary information concerning the nature of active particles (radicals, ions) participating in the active process from the composition of the Ko-polymer and from the kinetic data. The authors investigated the common polymerization of isobutyls with vinylidene chloride (in the "mass") in the temperature interval of -78 to 0° .

Card 1/4

SOV/20-124-3-39/67

On the Mechanism of the Low-temperature Polymerization of Monomers Under the Action of a Gamma-radiation

and of methyl-metacrylate with styrene in ethylchloride as solvent at -78 to $+25^{\circ}$. Polymerization was carried out in ampoules on a Co^{60} -source of 20,000 g-equivalents at an intensity of 230-250 r/sec. The degree of polymerization was not more than 10%. A diagram supplies data concerning the dependence of the copolymers on the composition of the original mixture for the system isobutylene-vinylidene chloride, which were determined in the course of polymerization at different temperature conditions. From these data the constants of the common polymerization α (for isobutylene) and β (for vinylidene chloride) were then determined according to the simplified equation for the integral composition. The following holds:

Polymerization temperature in $^{\circ}\text{C}$	α	β
-78	25	0
-40	1.27	0.21
0	0.03	1.3

Card 2/4

The composition of the common polymers formed depend to a

SOV/20-124-3-39/67

On the Mechanism of the Low-temperature Polymerization of Monomers Under the Action of a Gamma-radiation

considerable extent on temperature. Details are given. The data discussed in the present paper permit the following conclusions to be drawn: The joint polymerization of isobutylene with vinylidene chloride under the influence of a γ -radiation at low temperatures occurs according to the carbonium (karboniyeviy) mechanism or a similar mechanism. The authors further investigated the polymerization of styrene in an equimolecular mixture of styrene and methyl metacrylate in ethyl chloride as solvent. With decreasing temperature, the methyl metacrylate component in the copolymer decreases, which indicates an increase of the share of ion reactions in this process. The authors thank Academician S. S. Medvedev for discussing the results obtained. There are 2 figures, 2 tables, and 8 references, 4 of which are Soviet.

TEXT: The copolymerization of styrene (I) and α -eleostearic acid (II) dissolved in toluene was studied in the presence of benzoyl peroxide. Methods and results are presented. The copolymerization constants were determined, the differential and integral compositions of the polymers in the course of polymerization were calculated, and the conditions under which the copolymerization limit is reached were established. Small additions of II were found to inhibit the polymerization of I considerably. As a monomer, II is more reactive than I even though the reactivity of the radical of I is much higher than that of the radical of II. This fact causes

TITLE: Ion mechanism of polymerization under the action of nuclear radiations

SOURCE: Tashkentskaya konferentsiya po mirnomy ispol'zovaniyu atomnoy energii. Tashkent, 1959. Trudy. v. 1. Tashkent, 1961, 395-400

TEXT: The copolymerization of the following pairs of monomers was examined: isobutylene - vinylidene chloride (in the bulk) between -78 and 0°C ; styrene - methyl methacrylate between -78° and 25°C ; and isobutylene - styrene at -78°C (with ethyl chloride as solvent); acrylonitrile - styrene at -78°C (as solution in dimethyl formamide). Specially designed dilatometers and a Co^{60} source were used for the experiments. The copolymerization constants r_1 (for isobutylene), and r_2 (for vinylidene chloride) at -70 , -40 , and 0°C are 25, 1.27, 0.03, and 0, 0.21, 1.3, respectively. The compositions of the resulting copolymers are largely dependent on the polymerization temperature, and their concentration rises
Card 1/3

Ion mechanism of polymerization ...

significantly on cooling from -40 to -78°C. Therefore, low- and high-temperature polymerization under the action of radiation probably follow the ion and the radical mechanism, respectively. On the strength of these and other facts, gamma irradiation permits low-temperature copolymerization of isobutylene with vinylidene chloride according to the carbonium mechanism. The radiation polymerization of styrene and methyl methacrylate at 25°C follows the radical process. In the gamma polymerization of an equimolecular mixture of styrene and methyl methacrylate in ethyl chloride, the relative amount of the methyl methacrylate component in the copolymer drops rapidly with decreasing polymerization temperature. The resulting copolymers contain a component with a high concentration of styrene. Ion chains are formed in the low-temperature polymerization of styrene and methyl methacrylate according to the carbonium mechanism. The polymerization rate is reduced sharply by the addition of small amounts of isobutylene to styrene. Low-temperature radiation polymerization may also take place according to the ion mechanism. Not only the chemical structure of the monomer to be polymerized, but also the nature of the surrounding medium influences the polymerization mechanism. The mechanism of ion chain formation and the nature of the resulting ion pairs will later be studied. M. K. Yakovleva and L. P. Mezhirova assisted in the investigation.

TITLE: The carbanionic mechanism of polymerization under the action of gamma rays

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 3, no. 1, 1961, 99-104

TEXT: The present work studies the polymerization of acrylonitrile and its copolymerization with styrene under the action of γ -radiation at low temperatures for the purpose of explaining the reaction mechanism. Co^{60} was used as radiative source. The experimental temperatures ranged from -50 to $-112^{\circ}C$. Polymerization was performed in the solvents dimethyl formamide, triethyl amine, isopropyl amine, acetone, toluene, acetonitrile, propionitrile, ethyl chloride, heptane, ethyl acetate. The reaction rate was measured dilatometrically. (The volume change of the reaction mixture during polymerization was measured by the change of electric resistance of a platinum wire and a mercury thread inside the dilatometer capillary). The acrylonitrile polymers were separated from their solutions by means of

Card 1/3

The carbanionic mechanism of...

S/190/61/003/001/015/020
B119/B216

methyl alcohol and the styrene copolymers by a heptane - ether mixture. The copolymers were microanalyzed for C, H and N. In some cases the results were checked by infrared spectroscopy. At -78°C , and a dose rate of 128 rad/sec, the polymerization rate of acrylonitrile (initial concentration 3.5 mol/l) was $1.57 \text{ mol/l}\cdot\text{sec}\cdot 10^6$ in isopropyl amine, $6.7 \text{ mol/l}\cdot\text{sec}\cdot 10^6$ in triethyl amine, $9.7 \text{ mol/l}\cdot\text{sec}\cdot 10^6$ in dimethyl formamide and $2.1 \text{ mol/l}\cdot\text{sec}\cdot 10^6$ in the "bulk". The copolymerization constants were $r_1 = 33$ (acrylonitrile), $r_2 = 0.005$ (styrene). Results: Acrylonitrile polymerization occurs only in the solvents dimethyl formamide, triethyl amine and isopropyl amine, but not in solvents with electron acceptor properties. The composition of the copolymers obtained at -78°C by the above method and that of the analogous copolymers prepared by a radical reaction exhibit significant differences. The polymerization rate of acrylonitrile increases proportionately with the dose rate. A reduction of the reaction temperature from -50 to -112°C produces a great increase of reaction rate and molecular weight. The findings indicate a carbanionic reaction mechanism. The authors thank Ya. A. Tsarfin and K. G. Nogteva, both at Vladimirskiy nauchno-

TITLE: Study of the mechanism of polymerization by radiation. I.
Mechanism of carbonium polymerization of isobutylene and
styrene under the influence of gamma radiation

PERIODICAL: Vysokomolekulyarnyye soedineniya, v. 3, no. 5, 1961, 716-722

TEXT: The authors studied the kinetics and mechanism of separate and joint polymerization of styrene and isobutylene under the action of gamma radiation. According to published data, these monomers polymerize at low temperature following the carbonium mechanism. The kinetics of the process was studied dilatometrically. Isobutylene and styrene (2.5 moles/l) dissolved in ethylchloride were filled into reaction ampoule 1 (equipped with spiral capillary 2; Fig. 1) until the level A was reached. This process was carried out in vacuo and at the same temperature at which polymerization was performed. Capillary 3 was filled with Hg. In order to prevent boiling of the reaction mixture, sphere 5 was filled with the same mixture so that a counterpressure existed. The platinum wire 4 with the contacts 7 was con-

Study of ...

nected to a measuring bridge and, thus, the resistance was measured, which increased due to a decrease in volume during polymerization and simultaneous lowering to the Hg level in capillary 3. The mercury was collected in 6. Irradiation was carried out with Co^{60} at -78°C and a dosage of 106 rad/sec. Volume changes not caused by polymerization (i.e., due to heating during radiation adsorption) were corrected by a control dilatometer filled with ethylchloride, isopentene, and ethylbenzene. The composition of the copolymers was determined by Ya. A. Tsarfin and K. G. Nogteva (analiticheskaya laboratoriya Vladimirskego NIISA; Analytical Laboratory of Vladimir NIIS) by elementary analysis. Fig. 5 shows the composition of copolymers consisting of isobutylene and styrene. During the initial stage of copolymerization, the yield of copolymer is a linear function of time. The same holds for separate polymerization of monomers: styrene $20.1 \cdot 10^{-6}$ mole/l·sec; isobutylene $14.1 \cdot 10^{-6}$ mole/l·sec. Fig. 7 shows the copolymerization rate ω for different molar fractions of isobutylene. Fig. 9 presents $\log \omega$ as a function of the logarithm of the radiation dose I (14-110 rad/sec). Also $\log \omega = f(\log c)$ (c = concentration is a linear function for both monomers. The authors calculated the reaction constants from the data on the composition of the copolymers: r_1 (isobutylene) = 3.5; r_2 (styrene) = 0.33. In radiation polymerization and at low temperature, Card 2/8

Study of ...

S/190/51/003/005/007/012
B101/3218

isobutylene is more active than styrene. Polymerization proceeds according to the carbonium mechanism, similar to that in the presence of SnCl_4 . The molecular weights of the copolymers were determined by N. V. Makletsova and found to be: ratio isobutylene: styrene in initial mixture:

1.0 : 0.0	0.9 : 0.1	0.5 : 0.5	0.1 : 0.9	0.0 : 1.0	;	molecular weight:
80,000	55,000	27,000	35,000	70,000		

As is shown in Fig. 10, copolymerization at 0°C takes an entirely different course. In this case, the radical mechanism comes in play, but this does not lead to polymerization of isobutylene. The polymers obtained at 0°C contained chlorine. There are 10 figures and 25 references: 8 Soviet-bloc and 17 non-Soviet-bloc. TITLE: Studies of the mechanism of radiation polymerization. II. Mechanism of carbocation polymerization of styrene and methyl methacrylate under the action of γ rays

PERIODICAL: Vysokomolekulyarnyye soedineniya, v. 3, no. 6, 1961, 828-832

TEXT: Previous studies of the authors (Ref. 1: Dokl. AN SSSR, 124, 632, 1959) lead to the assumption that chains with ionic character form during copolymerization of an equimolar mixture of styrene and methyl methacrylate in ethyl chloride under the action of γ rays. The present work studies this influence in greater detail. Methyl methacrylate, treated with 3% soda solution, was washed with water, dried over Na_2CO_3 , distilled at 42.5°C at 101 mm Hg and stored in sealed evacuated ampules over dry ice. The kinetics of the process were determined dilatometrically, the polymerization at 25°C, 40°C, and -75°C. The polymer was separated a) by removing the solvent and unreacted monomer in benzene in the presence

Studies of the mechanism of radiation

of CuSO_4 , and b) by precipitating the polymer by means of methyl alcohol in the presence of hydroquinone. The composition of the copolymer was determined by ultimate analysis for carbon and hydrogen carried out in the Vladimirskiy NIIIS by Ye. A. Gorfir and K. S. Kostina. The infrared spectrum was taken in a solution containing 10 g of polymer to 1 l of CCl_4 at a thickness of 2.5 mm, with bands at 1725 cm^{-1} (CO group) and 700 cm^{-1} (benzene rings of polystyrene). Table 1 gives the copolymers obtained in 4.03 mole/l of ethyl chloride, isolated by means of a). The copolymers prepared in this way could contain a diolytic by-product of the reaction mixture. The copolymers prepared by b) (Fig. 2) contain more of the styrene component than those prepared by a). This is due to the formation of a low-molecular, non-soluble, CH_2OH soluble product containing more of the methyl methacrylate component than the copolymer prepared by b). It contained chlorine, had a molecular weight of 361 and showed strong absorption at 1725 cm^{-1} (CO group) and 700 cm^{-1} (benzene ring). The initial polymerization rate was determined from the curve sections in Fig. 4. Fig. 5 shows the dependence of styrene and methyl methacrylate polymerization on the composition of the initial monomer mixture. The

styrene concentration is a linear function of the monomer concentration. Table 2 illustrates the dependence of the styrene polymerization rate on the surface of the reaction vessel. At -78°C , the use of ampoules made of stainless steel reduced the rate of styrene polymerization. The polymer molecular weights at an initial molar ratio styrene : methyl methacrylate of 0.9:0.1 were determined by N. V. Makletsova by the light scattering method at 70,000 for polystyrene and 30,000 for the copolymer. In copolymerization under the action of γ -radiation, lowering of the reaction temperature from 25°C to -78°C increases the relative content of styrene component ($r_1(\text{styrene}) = 20$; $r_2 = 0.005$). On polymerization of these monomers under the action of γ -radiation at 25°C , $r_1 = 0.63$; $r_2 = 0.50$. In the case of a peroxide-initiated polymerization at 60°C , $r_1 = 0.52$; $r_2 = 0.46$. With cation catalysts, $r_1 = 10.5$; $r_2 = 0.1$ and with anion catalysts $r_1 = 0.1$; $r_2 = 6.0$. The copolymer composition and the dependence of the copolymerization rate on the composition of the monomer mixture (Fig. 5) indicate a carbonium mechanism of polymerization of styrene with methyl methacrylate at low temperatures under the action of γ rays. Fig. 5

shows that the addition of (~ 10 mole%) methyl methacrylate inhibits polymerization to a greater extent than the addition of isobutylene, but not as strongly as acrylonitrile addition. From this it is concluded that the inhibition increases with increasing electronegativity of the substituent at the double bond of the added monomer. TITLE: Copolymerization of acryl nitrile and ethylene under the effect of gamma radiation

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 5, no. 7, 1961
1015 - 1019

TEXT: The copolymerization of ethylene with acryl nitrile (AN) under the effect of gamma radiation of Co^{60} , 20,000 g-eqv rillum, is studied. The tests were performed at 20°C in solution of toluene, the pressure of the ethylene being 10 to 45 kg/cm² and the intensity of the dose 30 rad/sec. The ethylene obtained from ethanol contained the following impurities (in vol%): 0.05 propylene, 0.02 butylenes, 0.3 saturated hydrocarbons, 0.14 CO₂, 0.01 O₂. The AN had a boiling point amounting to 77.5 - 78.5°C. The polymerization was effected in steel ampullae with magnetic mixer. The ampullae were filled with AN dissolved in toluene, liberated from air by freezing and thawing in vacuum, and saturated with

ethylene under the above-mentioned pressure. The polymer suspensions obtained were rinsed with methanol, dried in vacuum, and then their content in nitrogen as well as their viscosity in dimethyl formamide at 26°C and with a concentration of the polymer of 0.35 to 0.75 g/dl. were determined. Data obtained: 1) for molar ratios of styrene: AN = 0.1:0.9 and 0.5:0.5 the yield of polymer is linearly dependent on the time of polymerization required to achieve a 40% conversion. For a ratio of 0.7:0.3 the rate of polymerization increases up to 25% conversion and then decreases; 2) the intrinsic viscosity of the polymers increases with the degree of conversion; 3) with long radiation (about 20 hr and more) and a molar part of the AN > 0.5 the polymers become insoluble due to cross linking; 4) the rate of polymerization increases with increasing concentration of the AN; 5) for all ratios the polymer contains relatively more AN than the initial mixture. In the range of concentrations of the AN from 0.1 - 1.0 molar parts, the equation $y = 0.718 + 0.046x + 0.0019x^2$ holds, wherein x is the content of AN in the initial mixture and y the content of AN in the polymer; 6) the calculated constants of copolymerization are: $r_1(AN) = 7, r_2 \approx 0. r_1$ de-

creases, however, if the content in AN exceeds 0.7 molar parts; 7) the following constants were calculated for the copolymerization of ethylene with CO, based on the data given by M. Brubaker et al. (see below): $r_2(\text{CO}) = 0.25$; $r_2(\text{C}_2\text{H}_4) = 0.57$. G. S. Kolesnikov, A. P. Sunrun, and T

A. Soboleva are mentioned. There are 7 figures, 2 tables and 10 references: 3 Soviet-bloc, and 5 non Soviet-bloc. The most important references to English-language publications read as follows: M. TITLE: Study of the mechanism of radiation polymerization.
III. Mechanism of carbonium radiation polymerization

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 3, no. 8, 1961,
1135-1139

TEXT: Previously, the authors had studied the effect of gamma radiation on polymerization and copolymerization of isobutylene, styrene, and methyl methacrylate (MMA) dissolved in ethyl chloride and shown that they proceed at low temperatures (-78°C) according to the carbonium mechanism (Mezhdunarodnyy simpozium po makromolekulyarnoy khimii, SSSR, Moskva (International Symposium of Macromolecular Chemistry, USSR, Moscow) June 14-18, 1960; Vysokomolek. soyed. 3, 716, 1961; *ibid.*, 3 828, 1961). Some ideas with regard to this mechanism are put forward in the present paper. The initiation of polymer chains is effected by interaction between a monomer molecule and a proton presumably originating from the solvent. The following experimental data are given in confirmation of this assumption:

Card 1/4

26292

Study of the mechanism of ...

S/190/61/003/008/005/019
B110/B220

- 1) The polymerization rate is a linear function of the monomer concentration;
- 2) radiolysis of ethyl chloride at 78°C yields a product closely related to dichlorobutene as to molecular weight (132) and refractive index ($n_D^{20} = 1.4812$);
- 3) at -78°C the polymerization rate of isobutylene "in mass"

($46.7 \cdot 10^{-6}$ mole/l·sec) is lower than in a solution of ethyl chloride (concentration of isobutylene 12.6 mole/l; $71.2 \cdot 10^{-6}$ mole/l·sec). The following mechanism is assumed: The growing carbonium ion ejects a proton which forms a free radical with the negative molecular ion (counter-ion) of the monomer. The participation of the negative monomer ion is proved by the fact that the polymerization is strongly inhibited in the presence of a monomer with electron-acceptor properties. The copolymerization of isobutylene and styrene as well as of styrene and MMA follows the equation:

$$\omega = \frac{[(\lambda + 1)(r_1 A^2 + 2AB + r_2 B^2) \cdot \omega_a \omega_b]}{[\lambda \omega_b r_1 A^2 + \chi \omega_a \omega_b AB + \omega_a r_2 B^2]}$$

where ω is the total rate of copolymerization; A and B are the concentrations of the monomers A and B, respectively; ω_a and ω_b are the rates of separate

Card 2/4

26292

S/190/61/003/008/005/019
B110/B220

Study of the mechanism of ...

polymerization of A and B, respectively; $\lambda = v_a/v_b$ is the ratio of the formation rates of active centers of A and B; $\chi = (k_{brA+B}/k_{incrA+B} + k_{brB+A}/k_{incrB+A})/v_b$, where k_{incr} = rate of chain growth; k_{br} is the rate of chain rupture. The two unknowns λ and χ can be determined experimentally from ω_a , ω_b , and from the copolymerization rates at different ratios of the monomers. Data obtained for the copolymers of isobutylene (A) and styrene (B): $\lambda = 4$; $\chi = 8 \cdot 10^6$; for styrene (A) and MMA (B) $\lambda = 10$; $\chi = 440 \cdot 10^6$. It was observed that the polymerization rate of styrene increased at -78°C with increasing surface of the reaction vessel. The authors established an effect that is analogous to that of solid admixtures observed by R. Worrall et al. (J. Appl. Rad. a. Isot., 4, 84, 1958). The monomer molecules adsorbed on the surface of the reaction vessel have a higher electron affinity than the molecules in the volume, and are able to capture secondary electrons. Thus, the lifetime of the carbonium ions effecting the polymerization process is prolonged. Moreover, the influence of the surface is confirmed by a reduction of the molecular weight of the

Polymerization of styrene and...

as oxidants (Table). Potassium ferrocyanide and ferrous pyrophosphate complex (IV) served as reducing agents. The rate of polymerization was determined either dilatometrically or from the yield of polymer (in ampule). Polymerization took place at 5°C with an excess of butadiene, styrene with peroxides dissolved in it (10% solution), and the calculated amount of emulsifier solution. A suspension of the ferrous pyrophosphate complex was added at a certain temperature by means of medical syringes. Substances used: (1) mercaptate (3% by weight added to water, ratio monomer:emulsifier 1:3); (2) potassium ferrocyanide. The temperature was varied between 0 and 50°C. Seven peroxides were investigated in amounts equivalent to 0.02 and 0.1% by weight of isopropyl benzene hydroperoxide. $K_4Fe(CN)_6$ was used in concentrations equimolecular to hydroperoxide. *p*-tert-butyl isopropyl benzene hydroperoxide (I) had the optimum rate of polymerization; that of ethyl isopropyl benzene peroxide, isopropyl benzene- (II), and ethyl benzene hydroperoxide was lower, that of dibenzyl hydroperoxide still lower, and that of benzoyl peroxide the lowest. Polymerization with H_2O_2 proceeds fast at the beginning, then it decreases strongly, since H_2O_2 and the reducing agent are readily soluble in water. With 0.2-0.5% by weight
Card 2/7

B110/B147

of II, only the initial rate increases. The total yield is lower than with 0.1 % by weight of II. Between 0.75 and 1 % by weight of II, initial rates and total yield are much lower. With 0.02-0.2 % by weight of I, initial rates increase. Since the total rate decreases at 0.2 % by weight, the dependence of the reaction rate on the hydroperoxide concentration is probably linked with the inhibiting effect of the decomposition products of hydroperoxide. With 0.1 % by weight of I and an equimolecular amount of $K_4Fe(CH)_6$, both total yield and initial rate increased with increasing temperature. The activation energies were determined according to the Arrhenius equation and found to be: $E = 8.6$ kcal/mole for II and $E = 5.7$ kcal/mole for I. Reduction of E by 3 kcal/mole at $\sim 0^\circ C$ corresponds to a 200-fold increase of the reaction rate. Since the rate is twice as high at $0^\circ C$, the pre-exponential factor in the Arrhenius equation increases by 10^2 times with decreasing activation energy of I. For the copolymerization of butadiene with styrene (ratio 70 : 30) at $5^\circ C$, the following was used: Nekal (2.8 and 1.4 % by weight added to water), 0.44 % by weight of ferropolyphosphate (related to iron sulfate) of the monomer. The ratio organic phase : aqueous phase was 1 : 4 (by weight). In the case of 0.34 %
Card 3/7

B110/B147

Polymerization of styrene and...

by weight of hydroperoxide of II (equimolar ratio to the monomer) optimum rate was achieved with IV. The highest yield was achieved with aryl-alkyl hydroperoxides (I and 1,1-diphenyl ethane hydroperoxide (III)) (Table). With an emulsifier concentration of 2.8 %, maximum conversion (70-75 %) was achieved after 2 hr with 0.2 % by weight of I and with 0.3 % by weight of III. With 0.34 % by weight of II, optimum conversion (~30 %) was achieved after 2 hr. Polymerization of I and IV with 1.4 or 2.8 % by weight of emulsifier was constant up to 30 % conversion, then the rate dropped. With 1.4 % by weight, the initial rate was lower and the decrease more distinct. With an addition of 0.1 % by weight of hydroperoxide + 0.26 % by weight of IV (after 1 hr new addition of 0.1 % by weight of hydroperoxide and 0.16 % by weight of IV), constant polymerization took place up to 60 % conversion. Thus, the consumption of the initiating system causes a decrease in rate. The efficiency of redox systems and initiators depends on the reactivity of the radical as well as on the solubility of the peroxide compounds in the aqueous phase and on the monomers. The lower the solubility in water, the lower the loss and the stronger the initiating action. I + IV cause a higher rate of reaction than II + IV due to lower activation energy and lower solubility in water. For II + IV, the redox reaction occurs at the

Polymerization of styrene and...

is achieved after 4 hr at a ratio 0.3 IV : 1 HP. The high rate of polymerization for systems with III is caused by the low solubility of III in water. The redox potential of III is -200 mv. In dissolved state, it reacts with IV, but dissolves only slowly. This causes the great depth of conversion. IV with high positive potential (420 mv) is soluble in water. The rate of initiating is determined by interaction of HP with III. Polymerization is not initiated during the unproductive reaction of III soluble NaHSO_3 and well soluble HP 1. NaHSO_3 and poorly soluble HP II initiate polymerization. The effect of IV on III at 20°C consists in the conversion of the Fe^{2+} from the Fe^{3+} ions, thereby the depth of conversion increases. There are 4 figures and 1 table. References to English literature: 1. G. I. Gerasimov, T. M. G. Gerasimov, T. M. G. Gerasimov, J. Chem. Soc. Faraday Trans. 2, 1964, 60, 1441; 2. G. I. RADIATION POLYMERIZATION OF TETRAFLUOROETHYLENE IN THE
SOLID STATE (USSR)

Bruk, M. A., ~~A. D. Abkin~~, and P. M. Khomikovskiy. IN: Akademiya nauk
SSSR. Doklady, v. 149, no. 6, 21 Apr 1961, 1322-1325.

S/020/63/149/006/014/027

The radiation polymerization of tetrafluoroethylene (TFE) in the solid state has been studied at the Physicochemical Institute imeni L. Yu. Karpov. Specimens of pure TFE were frozen by immersion in liquid nitrogen and irradiated from a Co^{60} source with an activity of 60,000 g-equiv of Ra or from an electron accelerator with an energy of 1.5 Mev. The yield of the polymers was determined gravimetrically following fast defreezing of irradiated specimens. The EPR spectra were recorded with the use of P3-1301 type devices; the absolute concentrations of radicals were evaluated by comparison of the signal areas of the sample and of a standard with

Card 1/2

AID Nr. 993-6 19 June

RADIATION POLYMERIZATION [Cont'd]

s/020/63/149/006/014/027

a known concentration of paramagnetic particles. It was shown that 1) the initial polymerization rate of TFE in the solid state increases with temperature, attains a maximum near the melting point, and drops sharply after melting; 2) the total activation energy of polymerization is 0.6 kcal/mol in the -196 to -155°C range and 1.6 kcal/mol at -155 to -131°C; 3) rapid annihilation of radicals takes place in the -180 to -140°C range and in the -80 to -50°C range; and 4) the character of the radical annihilation and changes in the EPR spectra observed at low temperatures suggest that these spectra are associated with the radical formed in the monomer, and the spectra observed at -150°C and above, to the radical in the polymer. Finally, it is assumed that the polymer radical has the structure

and is formed in the system as a result of the growth of the polymer chain.

TITLE: Copolymers of acrylonitrile and vinyl acetate

PERIODICAL: Khimicheskiye volokna, no. 1, 1962, 49 - 54

TEXT: The composition of copolymers of acrylonitrile (I) and vinyl acetate (II) in (a) aqueous emulsions, and (b) homogeneous dimethyl formamide solutions (DMF) with peroxide initiators in different steps of polymerization was studied. The following values were found for a: monomer:H₂O = 1:3, emulsifier concentration = 3% by weight of the monomer, K₂SO₅ concentration = 0.3% by weight of the monomer, temperature = 50°C; the values for b were: concentration of monomers in DMF = 4 moles/liter, benzoyl peroxide concentration = 0.048 moles/liter, temperature = 50°C. Copolymerization was first investigated in 30 - 40 ml dilatometers for a conversion of 10 - 15%. The copolymer obtained from an aqueous emulsion was coagulated by a 10% aqueous NaCl solution, that obtained from DMF by a 60 - 70% DMF solution. In this case, the copolymers were extracted by benzene. Further copolymerization in Card 1/4

Copolymers of acrylonitrile...

S/183/62/000/001/001/001
B110/B147

aqueous emulsions was investigated in a 6 liter reaction vessel in N_2 atmosphere ($\leq 0.05\% O_2$) in the presence of K_2SO_5 . The authors determined: X

(1) the composition according to nitrogen content (Kjeldahl), (2) characteristic viscosity of 0.5% solutions of the copolymers in DMF, (3) their solubility (qualitatively), (4) density, (5) vitrification temperature according to V. A. Kargin et al. (Ref. 6: ZhFKh, 23, 630 (1949)). When the degree of conversion was low, copolymers of different characteristic viscosities were obtained. The lower η_{char} of the copolymers obtained in DMF solution are caused by chain transfer through the solvent. The dependence of η_{char} on the initial monomer composition is caused by different reactivities of monomers and radicals formed from them. This dependence is practically the same for copolymers from a DMF solution and from aqueous emulsion. For an arbitrary initial component ratio, the copolymer is always enriched with I. The copolymerization constants ($r_1 = 4.2$, $r_2 = 0.05$) obtained according to L. Gindin et al. (Ref. 8: ZhFKh, 21, 1269 (1947)) show that the rate of addition of I to its own and to a foreign radical is higher than that of II. Since with

Card 2/4

S/183/62/000/001/001/001

B110/B147

Copolymers of acrylonitrile...

arbitrary initial monomer ratios I is faster consumed than II, only II polymerizes in many cases. Integral copolymer composition changes with the degree of transformation, with the content of I decreasing. Differential copolymer composition changes stronger than integral copolymer composition, with homopolymerization of II taking place when I is exhausted. The intramolecular distribution of chain links was calculated from the formulas for the distribution functions according to L. Gindin et al. (Ref. 11: DAN, SSSR, 56, 2, 177 (1947)). With a high content of I in the initial mixture, the macromolecules are made up of long links of I connected by 1 - 2 links of II. Copolymerization of I and II (initial molar fraction of I = 0.679) with 70% yield results in an equimolar ratio with an integral composition of ~80% M of I. Macromolecules of the copolymer (50:50) consist of successive sections of I and II with 1 - 10 links of each component. Solubility increases, and specific gravity and vitrification temperature decrease when the fraction of II is increased. The fraction of the copolymer enriched with II acts as a plasticizer in fiber production, and deteriorates the properties of the fiber (resistance to heat). There are 6 figures, 5 tables, and 12 references: 5 Soviet and 7 non-Soviet. The three most recent references to English-language publications read as

TITLE: Production of fiber-forming copolymers from acrylonitrile and vinyl acetate

PERIODICAL: Khimicheskiye volokna; no. 5, 1962, 16 - 21

TEXT: This second paper on copolymerization of acrylonitrile (AN) with vinyl acetate (VA) describes laboratory and pilot plant experiments in N₂ atmosphere at 50°C aimed at the production of copolymer fibers containing 3 - 20% VA, and lists the properties of the fibers. Results: A copolymer of the ratio AN : VA = 90 : 10 was found to have optimum properties. Because of the higher reactivity of AN, this was added in successive doses during the process, together with the regulator and the emulsifier, so as to obtain copolymers of constant composition. The inhibiting effect of O₂ contained in N₂ was suppressed by 0.03 - 0.05% hydrosulfite. Since the reaction velocity strongly increases owing to the redox system formed, N₂ was used with a maximum of 0.5 - 0.8% O₂. The following optimum conditions were found experimentally: ratio monomers : H₂O = 1 : 3; ratio AN : VA in Card 1/3

the initial mixture equalling 68 : 32; content of initiator (water-soluble peroxide) 0.7% of the monomer weight; emulsifier (MK (MK) or Sulfanole) 3.0%; regulator (Diproxid) 0.03%; duration of process 4 hrs, yield 70-78%. In the laboratory test, the fiber was spun from 14 - 16% solution of copolymer in dimethyl formamide. Oxidized hydrocarbons (C₁₂ - C₁₅) were used for the precipitation bath (90-100°C), and triethylene glycol for the drawing bath (100°C). In the pilot plant test, spinning was performed through spinnerets with 4800 or 12,000 openings, following a procedure developed for polyacrylic fibers, in a 40-60% dimethyl formamide precipitation bath. The "nitron B (V)" fiber showed a breaking length of 25 - 30 km, an elongation after embossing of 20-25%, and a shrinkage in boiling water of 25-30%. Increased shrinkage occurred with increasing VA content, fiber with 20% VA was poorly heat-resistant. The vitrification temperature was 80-82°C for 10% VA, and 65-70°C for 20% VA, as against 85-90°C for pure nitron (polyacrylic fiber). The new fiber can be colored by basic or disperse colorants. Colorability increases with increasing VA content. A VA content of 10-12% is recommended for the production of staple fiber, a VA content of 20% for fur manufactured from man-made fibers. There are 3 figures and 4 tables.

TITLE: The part played by the distribution of monomers between the phases in the emulsion copolymerization of acrylonitrile and vinyl acetate

PERIODICAL: Kolloidnyy zhurnal, v. 24, no. 5, 1962, 549 - 553

TEXT: The distribution of monomeric acrylonitrile and of vinyl acetate between the hydrocarbon phase and the liquid phase was examined at 50°C, both with and without the addition of MK (MK) as emulsifier. A likely reaction mechanism of the polymerization is suggested. The distribution by volume was determined after shaking together a mixture of monomers and water for one hour. The initial proportion by weight was 3:1. The proportionate amounts of acrylonitrile and vinyl acetate were determined by refractometry, applying a correction for the solubility of the hydrocarbon phase in water. The results are collected in Table 1 and Table 2. The ratio of acrylonitrile to vinyl acetate in the hydrocarbon phase is seen to be only slightly displaced, whereas considerable deviations appear

in the aqueous phase. The solubility of the monomers is slightly greater in soap solution than in water. Polymerization experiments carried out with different quantities of emulsifier indicated that the polymerizing reaction proceeds firstly in the soap micelle and later in the polymeric monomer particles. There are 4 figures and 2 tables.

TITLE: Kinetics of copolymerization of acrylonitrile and vinyl acetate

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 5, no. 3, 1963, 385-392

TEXT: To study the possibility of synthesizing fiber-forming copolymers, the kinetics of copolymerization of acrylonitrile (AN) and vinyl acetate (VA) was investigated in dimethyl formamide (DMF) and in aqueous emulsion. In DMF the concentration of components was 4 moles/liter and copolymerization was performed at 50°C with 0.048 moles/liter benzoyl peroxide. In aqueous emulsion the monomer : water ratio was 1 : 3 and potassium persulfate served as initiator. The following values were calculated from the equations developed in the thesis by Abkin (Fiziko-khim. in-t im. L. Ya. Karpova, M., 1951) for the reaction in DMF: $\lambda = 1$, $\theta = 40$, $r_1 = 4.2$, $r_2 = 0.05$, constant of cross termination $k_{tAB} = 8.78 \cdot 10^8$ liters/mole·sec, constant of the initiation rate $k_A = k_B' = 2.65 \cdot 10^{-8}$ liters/mole·sec. For copolymerization in the emulsion, the values were: $\lambda = 8$, $\theta = 170$, con-

stants of the rate of growth $k_{BB} = 1632$, $k_{AB} = 86$, $k_{AA} = 361$, $k_{BA} = 32,700$,
 $k_{tAB} = 3.73 \cdot 10^{10}$, $k_A = 22.4 \cdot 10^{-7}$, $k'_B = 2.8 \cdot 10^{-7}$ liters/mole·sec. The index
A refers to AN, the index B to VA. There are 3 figures and 2 tables.

TITLE: Carbanion mechanism of gamma ray initiated polymerization

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 5, no. 4, 1963, 473-478

TEXT: The Co^{60} gamma ray initiated polymerization of acrylonitrile (AN) and copolymerization of AN with styrene (St) and methyl methacrylate (MMA) are discussed. Results: (1) At -78°C the polymerization of AN initiated by gamma irradiation was successful in triethyl amine only, while at 0°C the electron donor or acceptor properties of the solvents (triethyl amine, ethyl chloride, acetonitrile or butyronitrile) had no effect on the polymerization. (2) When copolymerization of AN with St was initiated by gamma rays, copolymers enriched with AN formed at low temperatures, while at normal temperatures an azeotrope characteristic of the radical polymerization of these monomers was formed. (3) Copolymerization of AN with MMA, initiated by gamma rays, yielded in triethyl amine at -78°C a polymer enriched with AN, independently of the initial ratio of the monomers. $r_{\text{AN}} = 7.0$, $r_{\text{MMA}} = 0.05$, these values being close to those for catalytic

anionic polymerization. (4) The kinetics differs from that of radical polymerization. MMA polymerizes more slowly ($0.04 \cdot 10^{-5}$ mole/l·sec) than AN ($0.96 \cdot 10^{-5}$ mole/l·sec). (5) These differences confirm the carbanion mechanism suggested by the authors for the polymerization and copolymerization of AN by gamma irradiation at low temperatures. TITLE: Mechanism of heterogeneous polymerization of ethylene under the effect of ionizing radiations

PERIODICAL: Vysokomolekulyarnyye soyedineniya, v. 5, no. 4, 1963, 479-486

TEXT: A method was developed for determining the diffusion coefficient of ethylene in polyethylene by plotting the desorption curve, after the polyethylene had been previously saturated under pressure (up to 200 atm) with ethylene. The desorption-induced change in weight of the polyethylene was measured. The diffusion coefficient was at 25°C ~3.5, at 38°C ~6.0, at 50°C ~9.0. The solubility of ethylene in polyethylene is proportional to its volatility, and with constant volatility independent of the temperature. With constant temperature, the diffusion coefficient is independent of the solubility of ethylene. The specific surface and the pore diameter of the polyethylene was determined with crypton by the method of A. Zettlemeier, A. Chanda, E. Gamble (J. Amer. Chem. Soc., 72, 2752, 1950). The specific surface was dependent on the conditions of polymerization; it was (m^2/g): 20.2 with a dose of 62 r/sec, 300 atm, 70°C, irradiation time 10 hr; Card 1/2

Mechanism of heterogeneous ...

S/190/63/005/004/002/020
B1C1/B220

33.2 at 141/r sec, 400 atm, 25°C, 6 hr; and 18.0 at 141 r/sec, 400 atm, 25°C, 12 hr. Assuming cylindrical pores their internal diameter r_0 and wall thickness d are calculated: $r_0 = 1.66 \cdot 10^{-5}$ cm, $d = 6.32 \cdot 10^{-6}$ -

$1.69 \cdot 10^{-5}$ cm. Based on the cylindrical model and using the method of J. Crank (Mathematics of Diffusion, Oxford Univ. Press, London, 1957), a rate of ethylene addition at the radicals inside the polymer of 23.2 g/l·sec was found, whereas the experimental data vary between 8.5 and 45.0 g/l·hr. This difference is explained by the fact that the concentration of the reactive radicals inside the polymer is less than 10^{-3} mole/l. From the proportionality between rate of polymerization and specific surface it is concluded that the reactive radicals are mainly at the surface of the polymer. There are 4 figures and 3 tables.
