

Application of the Mises' Variables to the  
Problem of Spreading of the Flow of Laminar  
Jet Along a Wall

77994  
SOV/40-24-1-22/28

where

$$I_0 = \frac{E_0}{v u_0^2} \quad (3.1)$$

A recursive system of differential equations is gotten for the  $f_i$  with corresponding boundary and integral conditions. Graphs are given of the first three  $f_i$ . The author notes that the solution tends to the Blasius solution as  $\zeta \rightarrow \infty$  since the intensity of the jet diminishes downstream at large distances from the source and the flow velocity becomes constant. A graph is also given of the velocity profile  $u/u_0$  for  $\zeta/L_0 = 1.4$  as well as the profile for  $\zeta/L_0 = \infty$ , i.e., the Blasius profile for comparison. There are 3

TITLE: A plane half-bounded jet on a curvilinear surface

PERIODICAL: Zhurnal prikladnoy mekhaniki i tekhnicheskoy fiziki,  
no. 6, 1962, 60-67

TEXT: A solid cylindrical surface, located in an infinite space filled with a viscous fluid at rest, is considered. On the convex side of the surface there is a straight, infinitely thin slit-source parallel to the generators of the cylinder, and a jet of fluid with the same physical constants as the fluid occupying the surrounding space is projected from the source along the tangent plane to the surface. Experiments have shown that for a considerable portion of its path the jet flows round the surface and is not separated from it. This is attributed to a fall in the pressure at the surface, which is due to inertial forces on the jet. The Navier-Stokes equations for the problem are formulated, assuming that the fluid is incompressible and the motion is steady and laminar. The equations are then simplified by passing to dimensionless variables and using approximate expressions for the

Card 1/2

S/207/62/000/006/011/025  
E025/E114

thickness of the flow region and the radius of curvature  $R$ . The solution of the problem is sought in the form of a series in powers of  $R^{-1}$  in which the first term corresponds to a plane surface and the second term is a curvature correction. An expansion of the stream function in terms of arbitrary functions is then substituted into the Navier-Stokes equations, yielding a set of ordinary differential equations for the determination of the arbitrary functions and hence of the stream function. It is found that the solution for a curved surface cannot be found in terms of analytical functions and a procedure for numerical integration is outlined. Estimates are given for the coordinates of the point at which the jet separates from the surface. The cases where the jet is projected inside the surface and where the curvature of the cylinder is not constant are briefly discussed. There are 4 figures and 1 table.

TITLE: Experimental investigation of aerodynamic characteristics of astronomic telescope domes

SOURCE: Leningrad. Politekhnicheskiy institut. Trudy\*, no. 230, 1964. Tekhnicheskaya gidromekhanika (Technical hydromechanics), 132-136

TOPIC TAGS: telescope dome, aerodynamic characteristic, air resistance force, aerodynamic tunnel

ABSTRACT: An experimental study of the aerodynamic characteristics of astronomic telescope domes was conducted to determine the optimal shape of such domes. Models having various shapes (symmetrical and otherwise) were analyzed in an aerodynamic tunnel. A brief description of the apparatus and test procedure is given. Five different shapes were tested, and the results are given in graphs and discussed. It was found that domes symmetrical with respect to a vertical axis have the best aerodynamic characteristics, and that the air resistance

here,  $u$  and  $v$  are projections of the mean velocity vector on axes  $Ox$  and  $Oy$ ,  $\rho$  is fluid density,  $\tau$  is tangential friction stress and  $p$  is hydrostatic pressure. Observing boundary and integral conditions, the author obtains a solution to equation (1) as well as for the kinetic

system of common differential equations. The final solution was obtained by integrating that system while observing integral relations and boundary conditions. The pressure remains constant in this solution along the Oy axis, but varies along the Ox axis, and its distribution is parabolic. The pressure distribution in the central plane is also markedly distinct from ABC and DPMas.

AUTHOR: Akatov, A. K.

TITLE: Investigation of the staphylococcus alpha-toxin lethal effect on certain inbred lines of mice

SOURCE: Zhurnal mikrobiologii, epidemiologii i immunobiologii, no. 4, 1964, 81-87

TOPIC TAGS: staphylococcus alpha-toxin, lethal effect, inbred lines of mice, sensitivity difference, male toxin sensitivity, female toxin sensitivity, biomtric analysis

ABSTRACT: Sensitivity differences to the lethal effect of staphylococcus alpha-toxin were investigated in inbred lines of mice (BAL, B/c, C3H, C57BL, C57L, and CC57BR) and in control mongrel mice. All experimental animals and control group animals were divided into male and female groups to determine whether sex of animal also influences sensitivity as indicated in some literature sources. In the first of two experimental series, staphylococcus alpha-toxin doses of 0.0006, 0.0009, 0.013, and 0.02 ml were administered to groups of young mice weighing 15 to 18 g. In the second series doses of 0.007, 0.011,

1/2

Card-

ACCESSION NR: AP4031447

0.017, and 0.025 were administered to groups of older mice weighing 18 to 21 g. In both series each dose was administered to four similar groups consisting of 5 mice each and of the same sex. Animals were observed for 7 days following inoculation and checked twice each day to determine lethal effects of the toxin. Data were analyzed by biometric methods. Findings show that inbred lines of mice differ in their susceptibility and sensitivity to staphylococcus alpha-toxin in the following descending order: C3H, C57BL, control mongrel mice, C57L, and BAL B/c. Data on the CC57BR line was inconclusive. Age of animal does not appear to affect sensitivity. Female mice were found more sensitive than male mice. All animals displayed a higher sensitivity to staphylococcus alpha-toxin than to staphylococcus cultures, but variability of responses to toxin administration was lower than to culture injections. Orig. art. has: 3 tables.

Veterinariya, Vol 30, No 9, p 53

Furacylin is a new Soviet drug, 5-nitro-2-furfurylidenesemicarbazone, which proved to be effective in the treatment of acute cases of infectious follicular vestibulitis in cows and balanoposthitis in bulls.

270T76

It was also effective in the treatment of trypansomosis in camels and coccidiosis and mastitis in cows. Furacylin is a yellow, bitterish powder, somewhat soluble in water and in alcohol, but not soluble in ether. Its effectiveness is preserved for a long period of time if it is kept in jars made of dark glass. Furacylin solution prepared in cod-liver oil produced the best therapeutic effects.

Title : The Clinical Picture of Trichomoniasis in Bulls.

Orig Pub : Tr. Kirg. s.-kh. in-ta, 1956, vyp. 9, 205-208

Abstract : Trichomoniasis in bulls follows a course either of an acute and chronic balanoposthitis, or one without symptoms (Trichomonas-carrier condition). In an acute form, edema, hyperemia, painfulness of the glans penis and of the prepuce, and a discharge of the purulent exudate, are noticeable. Nodules are present on the glans penis. The potency is decreased. The trichomonads are localized in the prepuce. In the chronic form of disease, the symptoms are the same but the edema and painfulness of the

TITLE: Analysis of the results of measurements of cosmic-radiation doses in circumterrestrial space [Paper presented at the Conference on Problems of Space Medicine held in Moscow from 24-27 May 1966]

SOURCE: Konferentsiya po problemam kosmicheskoy meditsiny, 1966. Problemy kosmicheskoy meditsiny. (Problems of space medicine); materialy konferentsii, Moscow, 1966, 15-16

TOPIC TAGS: radiation dosimetry, cosmic radiation, solar flare, thermoluminescent dosimeter, radiation shielding, manned spaceflight, photodosimeter, ILK dosimeter

ABSTRACT:

The results of measurements of radiation in space taken at altitudes of 200-400 km have been analyzed. Dosimetry was performed by means

Card 1/3

L 08274-67

ACC NR: AT6036470

3.

of thermoluminescent integral dosimeters, ILK plates, and photodosimeters. The composition of radiation was studied using a set of nuclear photoemulsions. Dose measurement and study of the composition of radiation was performed behind polyethylene shielding of varying thickness. In addition, some of the thermoluminescent dosimeters were located behind lead, tin, and cadmium filters.

Polyethylene shielding blocks were spherical, with wall thicknesses of 5, 10, and 15 cm. Sets of dosimeters and photoemulsions were placed inside the shielding blocks as well as outside of them at four different points inside the cabin of the satellite.

The experiments established that the average cosmic-radiation dose amounted to between 16 and 20 mrad/diem. It was found that the thickness of shielding and the filters did not have a significant effect on the size of the dose. The doses obtained are in general agreement with doses obtained earlier on the Vostok spaceships.

Card 2/3

L 08274-67

ACC NR: AT6036470

The consistency of the doses obtained during the 1961-1965 period can be explained by the fact that on the trajectories in question the magnetic field of the Earth shields practically all of the low-energy spectrum of galactic radiation. Consequently, the main part of the dose was composed of high-energy particles whose intensity does not depend on solar activity to any great degree. This fact also explains the small changes in dose behind various thicknesses of shielding. [W.A. No. 22; ADD]
