TITLE: Photoproduction of positive pions from protons at photon energy 230 Mev and determination of the  $\gamma\pi p$  coupling constant

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 1, 1965,  
54-65

TOPIC TAGS: pion, muon, particle production, angular distribution, meson interaction

ABSTRACT: In view of the contradictory results of earlier measurements, the authors measured the differential cross section and the angular distribution for the photo-production of  $\pi^+$ -mesons from protons at photon energy 230 Mev for the c.m.s. angles 0, 38, 82, 90, 116, 138, 146, and 180°. The experiment was performed in the bremsstrahlung beam of the 265-Mev synchrotron at FIAN (Physics Institute of the Academy of Sciences). The experimental set-up is illustrated in Fig. 1 of the Enclosure. The apparatus and data-processing procedure are described in detail. The  $\pi^+$ -mesons of given energy were detected by a method involving identification of the particles from their momentum and range in matter, using a magnetic spectrometer and a detector of pion stoppings, comprising a plastic-scintillation-counter telescope con-

Card 1/3

taining a copper absorber of fixed thickness. The charged-particle trajectories were traced by the hot-wire method. Positive pions stopped in one of the counters were reliably identified from the  $\pi \rightarrow \mu$  decay, which occurred with a characteristic time  $\tau_\pi = 2.55 \times 10^{-8}$  sec. Momentum analysis of the particles was performed at 0 and 180°, and at the remaining angles only the stopping detector was used. The mean statistical accuracy was  $\pm (3-4)\%$ . Comparison of the experimental data with a calculation based on dispersion relations (M. I. Adamovich et al., Trudy FIAN v. 34, 1965, in press) and the use of a suitably plotted likelihood function yielded for the  $\gamma\pi p$  constant a value  $(0.63 \pm 0.11)ef$  ( $e$  = electron charge,  $f$  = interaction constant). The accuracy of the interaction constant was found to equal  $0.07 \pm 0.11$ . A

TITLE: Radar observations of Venus in the Soviet Union in 1964

SOURCE: AN SSSR. Doklady, v. 163, no. 1, 1965, 50-53

TOPIC TAGS: radio wave reflection, Venus radar observation, radio emission measurement, radar observation, radio astronomy

ABSTRACT: Radar observations of Venus at 40 cm were conducted between 11 and 30 June 1964 by the Institute of Radio Engineering and Electronics of the Academy of Sciences USSR. Frequency modulation and periodic linear frequency modulation of radiated signals were employed. Paramagnetic and parametric amplifiers were used at the receiver output. Signal analysis was performed by means of a 20-channel analyzer with a filter bandwidth of 1.2 cps for each channel. The reflected signal spectrum and measurements of the radial velocity of the motion of Venus were determined on the basis of the Doppler shift of the signal spectrum of the central frequency in relation to the radiation frequency. Frequency manipulation

was effected with the radiating signal shaped as two alternating telegraphic pulse packets at two carrier frequencies differing either by 62.5 or by 2000 cps. At each frequency, pulse duration and the intervals between transmissions were 4.096 sec. Radio wave reflection from the Venusian surface and measurements of the distance to Venus were effected with linear frequency modulation. The results of the measurements of the distance to Venus and of the radial velocity of its motion are shown in Fig. 1 of Enclosure, with the vertical sections showing rms error values, which till 23 June did not exceed 15 km for 5 min of observation (at a deviation of 4 kc) and after 23 June did not exceed 2 km (at a deviation of 32 kc). Measurement error for velocity did not exceed 2.5 cm/sec. Signal propagation time was calculated with an accuracy of  $\pm 5 \mu\text{sec}$ , and Doppler frequency, with an accuracy of  $\pm 0.05 \text{ cps}$ . The total rms error value for the initial data was  $\pm 400 \text{ km}$ .

TITLE: Method for determining statistical characteristics of phase coordinates in  
linear automatic control systems

SOURCE: Avtomatika i telemekhanika, no. 12, 1966, 47-57

TOPIC TAGS: <sup>LINFAH</sup> automatic control system, automatic control R and D, statistic  
analysis, automatic control design, automatic control technology

ABSTRACT: A method of determining mathematical expectation and crosscorrelation  
functions of phase coordinates is set forth; the method is applicable only to linear  
automatic control systems describable by  $\dot{x}(t) = A(t)x(t) + B(t)f(t)$ , with this initial  
condition:  $x(t)|_{t=0} = x_0$ , where  $x(t)$  is the n-dimensional vector of phase coordinates  
(a single-column matrix of phase coordinates);  $A(t)$  is the square, n-th order,  
matrix of coefficients that depends on random design parameters of system  $k_i$ ; with  
 $i = 1, \dots, m$ ;  $f(t)$  is the n-variate vector of external forces;  $B(t)$  is the diagonal  
matrix of coefficients that depends on  $k_i$ ;  $x_0$  is the n-variate vector of initial values

Card 1/2

UDC: 62 - 501.12

ACC NR: AP7002088

of the phase coordinates. The above system of differential equations is solved for  $t = T$ ; and the solutions have these forms:

mathematical expectation,  $M[x(T)] = \lim_{q \rightarrow \infty} M_q[x(T)]$ ,

crosscorrelation function,  $K_{xx}(T, T_1) = \lim_{q \rightarrow \infty} K_{xxq}(T, T_1)$ .

The number of realizations of random vector  $x(T)$  needed for determining the

mathematical expectation is:  $N = \prod_{i=1}^{n_1} q_i$ , where  $n_1$  - number of design parameters,

$q_i$  - number of realizations of the  $i$ -th design parameter. Thus, the number of  $x(T)$  realizations necessary for determining the mathematical expectation, in the above method, is equal to  $1/q^{n_1}$  the number of such realizations needed in the interpolation method and in the B. G. Dostupov method. With  $n_1 = 10$ , the above method becomes close to the Monte-Carlo method as far as the required amount of calculations is concerned. Orig. art. has: 55 formulas

TITLE: Analytical construction of regulators for two-channel systems with antisymmetric cross couplings

SOURCE: Ref. zh. Kibernetika, Abs. 7G76

REF SOURCE: Tr. Kazansk. aviat. in-ta, vyp. 87, 1965, 66-75

TOPIC TAGS: cross coupling, antisymmetric cross coupling, regulator, regulator design, two channel system

ABSTRACT: The problem of an analytical design for A. M. Letov regulators is generalized for a case of a two-channel system with cross couplings. The equation for the system has the form

$$d(p)x = k(p)u,$$
$$d(p) = p^n + \sum_{a=0}^{n-1} d_a p^a; \quad k(p) = \sum_{b=0}^m k_b p^b, \quad d_a \quad \text{and} \quad k_b$$

are complex numbers;  $x = x_1 + ix_2$  are the controlled coordinates;  $u = u_1 + iu_2$  are the actuation controls. Control  $u_1$  and  $u_2$  are selected from a condition of the functional minimum

Card 1/2

UDC: 62-505

ACC NR: AR6034634

$$I = \int_0^{n-1} \sum_{a=0}^{\infty} a_a (\rho^a x) (\rho^a \bar{x}) dt + \int_0^{\infty} \sum_{b=0}^{\infty} b_b (\rho^b u) (\rho^b \bar{u}) ds.$$

Necessary conditions for extreme conditions for the functional I are derived. The procedure for solving the derived equations is discussed. An example is analyzed. There is a bibliography of 4 items. Orig. art. has: 1 figure.

TITLE: Grapho-analytic method for approximate determination of transfer functions from their amplitude-phase characteristics

SOURCE: AN SSSR: Institut avtomatiki i telemekhaniki. Tekhnicheskaya Kibernetika (Technical cybernetics). Moscow, Izd-vo Nauka, 1965, 104-110

TOPIC TAGS: automatic control, automatic control system, transfer function determination

ABSTRACT: A grapho-analytic method is presented for approximate determination of the transfer function of a complex dynamic system on the basis of its attenuation-phase characteristics. This method can be applied to linear systems of minimum-phase as well as of nonminimum-phase types. The transfer function of the dynamic system is taken in the form of a rational fraction for which corresponding attenuation and phase characteristics (logarithmic characteristics)  $A(\omega)$  and  $\phi(\omega)$  as functions of unknown time parameters  $T_i$ ,  $T_k$ ,  $T_m$ ,  $T_s$ , and parameters  $\zeta_s$  and  $\zeta_m$  are written. The problem of determining the transfer function is reduced to determining unknown parameters on the basis of graphs of  $A(\omega)$  and  $\phi(\omega)$ . The basic idea of the method consists in the decomposition of the attenuation characteristic  $A(\omega)$  into characteristics of elementary

Card 1/2

L 17735-66

ACC NR: AT6006214

dynamic components and constructing their asymptotes. The time constants  $T_1$ ,  $T_k$ ,  $T_m$ , and  $T_s$  are determined on the basis of asymptotic attenuation characteristic of the components. To determine the unknowns  $\zeta_s$  and  $\xi_m$ , the system of S + M equations is derived. The sets of parameters  $\{T\}^1$  and  $\{\xi\}^1$  define the first approximation of the transfer function. To obtain more exact values of parameters of the transfer function, the method of successive approximations is applied. An iterative procedure is presented. The method is illustrated by an example in which the transfer function was approximately calculated from given attenuation and phase characteristics of a certain stable dynamic system. It is stressed that this method makes it possible to calculate the transfer function with any desired accuracy and can be applied to systems with delay components. Orig. art. has: 7 formulas.

TITLE: The study of the influence of the porosity of beryllium reflector<sup>19</sup> on the flow of thermal neutrons in horizontal beams

SOURCE: Moscow. Institut atomnoy energii. Doklady, IAE-957, 1965. Issledovaniye vliyaniya skvazhnosti berilliyevogo otrazhatelya na potok teplovykh netronov v gorizontalykh puchkakh, 1-32

TOPIC TAGS: reactor reflector, neutron beam, neutron flux

ABSTRACT: The intensity of strong neutron fluxes ( $10^{10}$ – $10^{11}$  n/cm<sup>2</sup>·sec) at the exit of experimental reactor beams is in part determined by the flow of thermal neutrons at the header of the beam and by its cross section. In turn, these depend on the properties of the reflector. Since the authors were unable to imitate on the critical stand the active zone with the required spectral composition of the neutrons, they imitated the "thermal" active zone by establishing the appropriate distribution of the thermal neutron flux within the beryllium reflector. This was achieved by placing a 0.5-mm thick cadmium filter between the active zone and the reflector. The present article describes the critical stand used and the methodology of the

TITLE: Determination of the optical parameters of the planets from observations  
near opposition

19

SOURCE: Ref. zh. Astronomiya, Abs. 11.51.514

REF SOURCE: Vestn. Khar'kovsk. un-ta, no. 4, 1965, ser. astron., vyp. 1, 99-102

TOPIC TAGS: planetary atmosphere, optic measurement, optic property, Jupiter planet

ABSTRACT: It is noted that for small values of planetary phase angle the use of the least squares method to determine the optical parameters of the planetary atmosphere and surface leads to a very poorly specified system of normal equations. A method for determining the optical parameters of the planets from observations near opposition is proposed which, in the author's opinion, allows this difficulty to be overcome. This method is based on the use of dispersion analysis and permits finding the most probable values of the optical parameters and also the greatest number of parameters which can be determined from the observation data. Some results of data analysis of photographic photometry of Jupiter are presented as an example.

The Wind-Power Resources of Voronezhskaya Oblast

The purpose of the work is to clarify the reserves of wind energy in the territory of Voronezhskaya Oblast's. The mean annual velocities of the wind according to a number of stations in Voronezhskaya Oblast are reduced to the altitude 15 meters of a wind gauge, and corrections made for local conditions. The largest number of days with strong wind is observed in January and February, the least in the summer months. The largest number of days with calm is observed in summer. The presented table of mean annual powers of an ideal wind engine, according to data of the meteorological stations of Voronezhskaya Oblast, is computed by means of the formula  $N = 0.000481 D^2 v^3 E_{max}$ , in kilowatts, where  $D$  is the diameter of the wheel,  $v$  is the wind velocity, and  $E_{max}$  is the maximum coefficient of utilization of wind energy of the ideal windmill ( $E_{max} = 0.593$ ). The wind velocities chosen were the mean annual velocities reduced to height 15 meters above the surface of the earth, and corrected for local conditions surrounding the wind gauge. A table of mean annual powers of a wind engine was computed taking into account the frequency of wind velocities from 3 to 10 meters/second according to the formula:  $N =$

0.000481 ( $D^2E/n$ ).( $v_3^3n_3 + \dots + v_{10}^3n_{10}$ ), in kilowatts, where the  $v$ 's are the operating wind velocities from 3 to 10 meters/second, and the  $n$ 's are the frequencies of the velocities corresponding;  $n$  designates the sum of the  $n$ 's. If in the table of the mean annual powers of a wind engine all the data are multiplied by 0.65 (i.e., coefficient 0.38 is used instead of 0.593), then one obtains the power of an actual wind engine. TITLE: Manufacture of Steel From High-P Cast Iron (Proizvodstvo stali iz vysokofosforistogo chuguna)

PERIODICAL: Sb. Mosk. in-t stali, 1957, Vol 37, pp 281-304

ABSTRACT: An analysis of 120 experimental smeltings performed in metallurgical furnaces employing air with 25-30% of O<sub>2</sub>. By employing O<sub>2</sub> the duration of the smelting process is reduced by 8% in the case of silica-brick furnace crowns (SC) and by 33% in the case of furnaces with basic crowns (BC); this reduction in time is accomplished primarily through a foreshortening of the melting and finishing stages. As the content of O<sub>2</sub> is increased from 25 to 30%, the duration of the smelting process diminishes continuously by 6.5-10.7% (in case of SC) and 14-36% (in the case of BC). Introduction of O<sub>2</sub> into the flame, increasing the amount of ore in the upper layers of friable ingredients, smelting procedures which allow slag to remain on the bottom of the hearth - all these measures speed up the processes of slag formation, deposphorization, and

Card 1/2

SOV/137-58-8-16493

Manufacture of Steel From High-P Cast Iron

saturation of slag with  $P_2O_5$ . Compared with smelting operations performed without oxygen in furnaces with SC's, the introduction of  $O_2$  into the flame reduced the fuel consumption in furnaces with BC's by 15-18%. Annual output of furnaces employing  $O_2$  increased by 5% in the case of SC furnaces and by 30.8% in the case of BC furnaces in comparison with BC furnaces employing no oxygen. The production cost of steel smelted in BC furnaces employing  $O_2$  is less by 3 rubles than the cost of regular steel. Employment of phosphate slags will reduce the production costs by 17.6 rubles. Additional capital expenditures connected with the employment of  $O_2$  can be recovered within approximately four years.

**PURPOSE:** This collection of papers is intended to furnish information on industrial

resources in Siberia and to provide a basis for future developmental

planning in the field of ferrous metallurgy.

**CONTENTS:** The collection is a summary of the proceedings of the Ferrous Metallurgy

Section of the Joint Conference of Representatives of the Academy of Sciences

USSR, the Soviet Planning Commission, the Council of Ministers USSR on the

Development of the Industrial Resources of Siberia. The collection deals

with four main areas of development in Siberia (part 1) Mineral resources;

(2) the fuel base; (3) prospects for the development of various metallurgical and

problems in development of electric power. A list of the 112 members of

the section with their affiliations is given in the Appendix. References

accompany several of the articles.

AUTHOR: Aleksandrova, A. K.; Byzova, N. L.; Mashkova, G. B.

TITLE: Experiments on the dissemination of precipitating contaminants from a point source in the lower atmosphere

SOURCE: Issledovaniye nizhnego 300-metrovogo sloya atmosfery\*. Moscow, 1963, 3-13

TOPIC TAGS: meteorology, air pollution, precipitating contaminant, point source contamination, lower atmosphere, turbulent diffusion

ABSTRACT: In calculating the diffusion of either precipitating or weightless contaminants in the boundary layer of the atmosphere, a phenomenon which depends both on the properties of the contaminant particles and on the turbulence of the air, the maximum concentration of contaminants and the distance of this point from the source are of considerable interest. The authors therefore present the results of 53 experiments, and derive formulas for these parameters on the basis of 2 systems of calculation, assuming either that the coefficient of vertical turbulent diffusion increases linearly with height, or that it is independent of height. For this purpose, 4 types of atmospheric stratification were distinguished (indifferent stratification and 3 degrees of instability), and inversions were not considered. As shown by graphs relating the height of the source to the dis-

Card 1/2

ACCESSION NR: AT4010218

tance between it and the point of maximum contaminant precipitation, as well as the relationships between atmospheric turbulence and the maximum contaminant concentration or length of the contaminated zone, the distance from the source to the area of maximum contaminant density, corrected for the effect of gravity, was proportional to the height of the source within each type of stratification and within the altitude range of 25-300 meters (error of  $\pm$  25%). The parameters of horizontal diffusion were determined by the type of stratification, while the position and magnitude of the maximum contaminant density and the length of the contaminated zone were determined by the ratio between the gravitational forces and the turbulence. At relatively high turbulence, the first type of calculation yielded better results for the maximum contaminant density, but the second type of calculation was preferable for determining the length of the contaminated zone; at relatively low turbulence, the method of calculation was immaterial. AUTHOR: Aleksandrova, A. K.

TITLE: A method of investigating the dispersion of an artificial aerosol in the surface layer

SOURCE: Izuchenie pogranichnogo sloya atmosfery s 300-metrovoy meteorologicheskoy bashni. Moscow, 1963, 155-159

TOPIC TAGS: meteorological tower, artificial aerosol, polymethyl methacrylate

ABSTRACT: The 300-meter meteorological tower has been used for an experiment involving the propagation of admixtures in the surface layer. The admixture used was a luminescent polymethyl methacrylate powder, whose advantages were described in the preceding article in the monograph. A special apparatus, illustrated and described in the text, was used for introducing the aerosol into the atmosphere. The apparatus holds 10 kg of powder and can introduce it into the atmosphere at the rate of 0.2 to 2 kilograms per hour. The particles were trapped at distances of 15 to 20 kilometers from the tower. Conclusions are drawn concerning the influence of the underlying surface on the transport of the admixture. Particles were trapped at 50 to 100 stations at distances of 25 meters to 1 kilometer apart. The processing method is described. Orig. art. has: 5 figures.

Behavior of the glass electrode in nonaqueous solutions.  
IV. Errors of the glass electrode in the acid and the alkali-  
line region in ethanol and in ethanol-water mixtures.  
N. A. Izmailov and A. M. Aleksandrova. *Zhur. Osnovy Khim.* (J. Gen. Chem.) 19, 1403-15 (1949); cf. C.I. 41,  
1144g.—In MeOH, EtOH, and in mixts. EtOH + H<sub>2</sub>O, 1144g.—In MeOH, EtOH, and in mixts. EtOH + H<sub>2</sub>O,  
the calibration curve of the Hughes and the MacInnes and  
Dole glass electrodes in the alk. region passes through a  
max. With increasing amt. of EtOH, the max. moves to  
more strongly alk. values. In the acid region (HCl), the  
sign of the deviation from linearity between the potential  
and the pH is opposed to that in the alk. region. The  
calibration curve passes through a min. which shifts to less  
acid values with increasing amt. of EtOH. The ion-ex-  
change coeff. K increases from H<sub>2</sub>O to the abs. alcs. Thus,  
from K = 6.31 × 10<sup>-11</sup> in H<sub>2</sub>O, it increases, for the glasses  
of Hughes and of MacInnes and Dole, to 8.0 × 10<sup>-11</sup> and  
2.0 × 10<sup>-11</sup>, resp., in abs. EtOH, and to 2.82 × 10<sup>-11</sup> and  
2.82 × 10<sup>-11</sup>, resp., in abs. MeOH. While the glass elec-  
trode remains perfectly usable in mixts. of EtOH and  
MeOH with H<sub>2</sub>O, the range of its applicability becomes  
narrower with increasing alc. content. N. Thom

C# ALEKSANDROVA, A.M.

Behavior of the glass electrode in the acid region. N. A. Imaikov and A. M. Aleksandrova (A. M. Gor'ki State Univ., Kharkov). Doklady Akad. Nauk S.S.R. 71, 811-13(1953).—The potential  $E$  of a Hughes glass electrode in  $3\text{N}$  and in  $5\text{N}$  HCl and 3-11 M LiCl is a linear function of the activity of the  $\text{Cl}^-$  ions as determined by the e.m.f. in a  $\text{Ag}|\text{AgCl}|\text{Cl}^-$  cell. The same linearity, but with a somewhat different slope, holds in solns. of NaCl in 3 N HCl, and in solns. of  $(\text{NH}_4)_2\text{SO}_4$  of varying concn. in 3 M  $\text{H}_2\text{SO}_4$ . Consequently, in the acid region, the glass behaves as a reversible electrode towards the anions, and its  $E$ , at a given low pH, is affected by the concn. of the anions. N. Then

Univ.), Zhur. Otschchet Khim. (J. Gen. Chem., U.S.S.R.)  
30, 2137-38 (1960); cf. C.A. 49, 1430d.—Glass electrodes  
of Hughes (I) and of MacInnes-Dole (II) glass were cal-  
ibrated at pH from 0.3 to -1.4, detd. with the quinhydrone  
electrode (against  $\text{H}_2\text{SO}_4$  0.1437 M in glacial AcOH) in  
the following solns. in glacial AcOH:  $\text{PhNM}_2$ , 1 M (pH  
8.3);  $\text{AcONa}$ , 1.0 N (8.1);  $\text{AcONa}$  0.25 N (7.6);  $\text{AcONa}$   
0.1 N (7.38);  $\text{AcONa}$  0.01 N (6.7);  $\text{AcONa}$  0.1 N +  $\text{HClO}_4$   
0.1 N (3.3);  $\text{HClO}_4$  0.05 N (3.4);  $\text{HClO}_4$  0.1 N (2.1);  
 $\text{HClO}_4$  0.3 N (1.4);  $\text{H}_2\text{SO}_4$ , 0.004 M +  $\text{AcO}^-$  10% (0.3);  
 $\text{H}_2\text{SO}_4$  0.007 M +  $\text{AcO}^-$  10% (-0.3);  $\text{HClO}_4$  0.02 N +  
 $\text{AcO}^-$  10% (-1.4). In aq. soln., electrode I showed a break  
at pH = 0.3, and II a deviation from linearity in the same  
region, but in glacial AcOH both electrodes showed a break  
at pH = 1.3. The potentials  $E$  of both electrodes varied  
linearly with the pH from 1.3 to 2.6, with the slopes  $\Delta E/\Delta \text{pH}$   
= 88.6 for (I) and 88.5 for (II), resp. Consequently,  
both electrodes were applicable for pH measurements in  
that range. Acid hysteresis was absent. Titration of  
 $\text{MeC}_6\text{H}_4\text{SO}_3\text{H}$  with  $\text{PhNM}_2\text{AcOH}$  in glacial AcOH with  
electrode I gave rapid establishment of the potentials (2  
min.) and a sharp peak of  $\Delta E$  against the vol. of reagent  
added.

Electrochemistry

Use of glass electrode in nonaqueous media. N. A. Izmailov and A. M. Aleksandrova. Izdat. Komiitata po Khim. Akad. Nauk S.S.R., Otdel. Khim. Nauk (1954) 140-02(1952); cf. C.A. 46, 4933d.—Over a wide pH interval, 2 electrodes were calibrated for mixts. of H<sub>2</sub>O and O<sub>2</sub>, 20, 71.0, 88.5, 93.5, and 100% EtOH by wt. Also 1 electrode was calibrated for H<sub>2</sub>O, abs. EtOH, and abs. MeOH. The app. is described. The electrodes were sphere shaped, like those of Gaber, but one was made of the glass used by Hughes and the other of the glass used by Maclennan and Dole. The pH of the alc. solns. used was measured by H electrode and compared against a standard, 0.1N HCl in the corresponding soln. Thus, activity was expressed on the scale pH<sub>soln.</sub>. Potentials of the electrode of Hughes glass were plotted against pH. All the curves were similar. In the middle pH range changes were proportional, but a min. occurred somewhere below pH 4 and a max. somewhere above pH 10. In the alk. range a cause of deviation was the differences of the exchange of H ion and Na ion between glass and soln. for different glass compns. For each electrode pH<sub>max.</sub> and K (const. of exchange of ions in glass) were detd. As alc. content increased, K increased because the activity was changed. As alc. content increased, the straight-line portion of the curve was shortened and this was the only limitation on the use of the glass electrode in nonaq. solns. In the middle pH range, pH did not depend on media. When the electrode of Hughes glass was used with H<sub>2</sub>O, abs. EtOH, and abs. MeOH, the differences in curves were explained by differences of phase and diffusion potentials. When the electrode of M. and D. glass was used with H<sub>2</sub>O and 88.5% EtOH, the curves were identical until pH 10, after which point alc. had a max. at a lower point than water had. 25 references. **Behavior of the glass electrode in acids.** N. A. Izmailov  
and A. M. Alekseevskaya [A. M. Gor'ki State Univ., Khar-

kov, Sverdlovsk Oblast Khim., Akad. Nauk S.S.R.]

S.R. 1, 173-8(1953); cf. C.A. 45, 4581d.—To det. the effect of anions on the calibration curve of the glass electrode in acids, measurements were made with a Hughes glass electrode in aq. solns. of HCl, H<sub>2</sub>SO<sub>4</sub>, and H<sub>3</sub>PO<sub>4</sub>. In all acids E vs. pH curves passed through a min., the position of which depended on the anion as well as on the concn. of the acid and the compn. of the glass of the electrode. In HCl at low pH beyond the min., the glass electrode acted irreversibly towards the anion. In H<sub>2</sub>SO<sub>4</sub> at 0.1 N, at 0.4 pH (10-16N), at 0.4 pH (25-30N), and in HCl at 0.2 pH (1-2N), E vs. log a ( $a$  = mean activity) in H<sub>2</sub>SO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, and HCl gave min. at log a 0.65, 2.1, and 0.17, respx. E vs. log a<sub>H+</sub> in HCl was a straight line, i.e., there was a straight line almost vertical to the log a<sub>H+</sub> axis down to the lowest E where it became horizontal. At 0.1 N there was a wide min. at a high value of E, and this was concluded that the error of the glass electrode in acids could not be due to the change in the H<sub>3</sub>O<sup>+</sup> activity in the solns., but rather to the likelihood that the electrode in acids acted an ionization function to the known H<sup>+</sup> function. In acids the electrode beyond the min. acted reversibly towards the anion. — I. Democatis

ALEKSENDROVICH, D. M.

In the W electrodes and the glass electrode the potential change was 0.05%. The relation of  $E$  vs. pH did not change with time but the abs. values of  $\Delta E$  shifted toward the pos. side and therefore, daily calibration of W electrodes is recommended. In the range of 4-14 pH the  $\Delta E$  vs. pH for a W electrode was linear (slope coeff. 0.05), thus it can be used as a gas H<sub>2</sub> electrode. W electrodes for detg. the pH in nonbuffered solns. (natural waters) did not give satisfactory results. Sb electrodes were used satisfactorily for detg. the pH in the interval of 5-8 in buffered solns. as well as in natural waters. As a rule the Sb electrodes gave more accurate results than did a glass electrode.

## TITLE:

An Accelerated Method for the Determination of Germanium in  
the Ashes of Coal Minerals (Uskorennyy metod opredeleniya  
germaniya v zole iskopayemykh ugley)

## PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 2, p 161 (USSR)

## ABSTRACT:

In the method described the coal sample is fused by heating in phosphoric acid and treated with hydrochloric acid; then the germanium chloride which has formed is distilled off and the germanium is determined colorimetrically with phenol fluorone. In comparison with the analogous analysis of ores by Strickland (Ref 1) twice as much phosphoric acid and no nitric acid is used in the present case. Coal samples (brown coal, types D, G, PZh, K, and PS) were determined by the method described and at the same time by a method in which the decomposition was performed in a mixture of hydrofluoric acid and sulfuric acid. A comparison (Table) of the results showed a remarkable agreement. In the presence of larger quantities of chlorides (more than 10%) losses of germanium may occur in the fusion process, as was shown by I. P. Alimarin and B. N. Ivanov-Emin (Ref 2) in the case of the hydrofluoric acid - sulfuric acid mixture. Duration of analysis by the method described:

TITLE: Selection of coal ashing conditions for germanium determination

52

SOURCE: Zavodskaya laboratoriya, v. 29, no. 7, 1963, 797-799

TOPIC TAGS: germanium, germanium determination, ashing, coal ashing, ashing temperature, heating rate, ash content, Ge

ABSTRACT: The behavior of germanium during the process of ashing of various coal samples was investigated in relation to the rate of temperature increase, the amount of mineral admixtures, the total sulfur content of the coal, and the ashing temperature. Five-gram samples of coal were placed in a furnace, the temperature raised at rates of 3.5 and 200 per minute until a final temperature of 550°C was reached, at which the ashing was continued until completed. The ash was analyzed for germanium, and it was found that in a brown coal sample with 13.41% ash the loss of germanium at a 3.50-increase rate amounted to 2.3% of its original content, while at an increase rate of 200 per minute the germanium loss amounted to 10.0%. On the other hand, a furnace-type bituminous coal with a 4.46% ash content lost (under identical ashing conditions) 2.7% and 6.7% respectively of the original germanium content. In

Card 1/2

L 15668-63

ACCESSION NR: AP3004220

order to check the effect of ash on the loss of germanium during the ashing process, each sample was separated into two fractions by difference in specific gravity, the one floating on top of a nonspecified fluid, the other settling. The ash content of the floating fractions of the same brown and bituminous coal samples amounted to 2.54% and 1.35% respectively, as against 26.17% and 38.81% in the settling fraction. After ashing at the 3.5C-rate, the losses of germanium amounted to 0.4% and 8.1% in the floating fractions, as against 2.5% and 0.0 in the settling fractions, thus placing emphasis on the kind of coal being ashed. The recommended procedure for the ashing of coal samples for germanium determination consists in a staggered increase of temperature at a rate of 3.5C per minute, with a maximum of 700C-800C, and duration of 3.5-4 hours. Orig. art. has: 2 tables.

1140 Spectrum excitation by a current  
from the anodes of a thermite  
cylinder and S. P. Davydov, *Zhur. Fiz.*  
*Mashinostroyeniya*, 1955, (4), 51-53; *Izv. Akad.*  
*Nauk Khim.* 1955, Abstr. No. 25 000. The analysis of  
the borides of Zn, Pt, Sn, Ni and Fe is carried out  
by using a low-current generator of powerful im-  
pulse discharges (filter band). The sample is cast  
in a metal mould and cut in two pieces. Before the  
analysis, the surface of the block is covered with a  
thin layer of an insulating varnish.

The spectrum is recorded on a photographic plate  
with a time exposure of 100 min. The lines used for the  
analysis are—Sn 2849.0 and Cu 2894.1; Pt 2819.4, Fe 2735.7 and Cu 2861.1.

The spectrum during work on the spectrometer  
with standards the mean square error was 1.1%  
(Zn 1.4%, Pt 1.0% and Fe 1.1%).

PURPOSE: This book is intended for scientists and researchers in  
the field of spectroscopy, as well as for technical personnel  
using spectrum analysis in various industries.

COVERAGE: This volume contains 177 scientific and technical studies  
of atomic spectroscopy presented at the 10th All-Union Conference  
on Spectroscopy in 1956. These were carried out by  
members of scientific and technical institutes and include  
extensive bibliographies of Soviet and other sources. The  
studies cover many phases of spectroscopy: spectra of rare earths,  
uranium production, physicochemical methods for controlling  
optical dispersion, theory, spectrum analysis of ores  
and minerals, photographic methods for quantitative spectrum  
analysis of metals and alloys, spectral determination of  
hydrogen content of metals by means of isotopes, tables, and  
atlasses of spectral lines, spark spectrographic analysis,  
statistical study of variation in the parameters of calibration  
curves, determination of traces of metals, spectrum analysis in  
metallurgy, thermochrometry in metallurgy, and principles and  
practice of spectrochemical analysis.

TITLE: Photoproduction of positive pions from protons at photon energy 230 Mev and determination of the  $\gamma\pi p$  coupling constant

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 1, 1965,  
54-65

TOPIC TAGS: pion, muon, particle production, angular distribution, meson interaction

ABSTRACT: In view of the contradictory results of earlier measurements, the authors measured the differential cross section and the angular distribution for the photo-production of  $\pi^+$ -mesons from protons at photon energy 230 Mev for the c.m.s. angles 0, 38, 82, 90, 116, 138, 146, and 180°. The experiment was performed in the bremsstrahlung beam of the 265-Mev synchrotron at FIAN (Physics Institute of the Academy of Sciences). The experimental set-up is illustrated in Fig. 1 of the Enclosure. The apparatus and data-processing procedure are described in detail. The  $\pi^+$ -mesons of given energy were detected by a method involving identification of the particles from their momentum and range in matter, using a magnetic spectrometer and a detector of pion stoppings, comprising a plastic-scintillation-counter telescope con-

Card 1/3

L 1570-66  
ACCESSION NR: AP5019216

taining a copper absorber of fixed thickness. The charged-particle trajectories were traced by the hot-wire method. Positive pions stopped in one of the counters were reliably identified from the  $\pi \rightarrow \mu$  decay, which occurred with a characteristic time  $\tau_\pi = 2.55 \times 10^{-8}$  sec. Momentum analysis of the particles was performed at 0 and 180°, and at the remaining angles only the stopping detector was used. The mean statistical accuracy was  $\pm (3-4)\%$ . Comparison of the experimental data with a calculation based on dispersion relations (M. I. Adamovich et al., Trudy FIAN v. 34, 1965, in press) and the use of a suitably plotted likelihood function yielded for the  $\gamma\pi p$  constant a value  $(0.63 \pm 0.11)ef$  ( $e$  = electron charge,  $f$  = interaction constant). The accuracy of the interaction constant was found to equal  $0.07 \pm 0.11$ . A

TITLE: Radar observations of Venus in the Soviet Union in 1964

SOURCE: AN SSSR. Doklady, v. 163, no. 1, 1965, 50-53

TOPIC TAGS: radio wave reflection, Venus radar observation, radio emission measurement, radar observation, radio astronomy

ABSTRACT: Radar observations of Venus at 40 cm were conducted between 11 and 30 June 1964 by the Institute of Radio Engineering and Electronics of the Academy of Sciences USSR. Frequency modulation and periodic linear frequency modulation of radiated signals were employed. Paramagnetic and parametric amplifiers were used at the receiver output. Signal analysis was performed by means of a 20-channel analyzer with a filter bandwidth of 1.2 cps for each channel. The reflected signal spectrum and measurements of the radial velocity of the motion of Venus were determined on the basis of the Doppler shift of the signal spectrum of the central frequency in relation to the radiation frequency. Frequency manipulation

Card 1/5

L 60859-65

ACCESSION NR: AP5018071

was effected with the radiating signal shaped as two alternating telegraphic pulse packets at two carrier frequencies differing either by 62.5 or by 2000 cps. At each frequency, pulse duration and the intervals between transmissions were 4.096 sec. Radio wave reflection from the Venusian surface and measurements of the distance to Venus were effected with linear frequency modulation. The results of the measurements of the distance to Venus and of the radial velocity of its motion are shown in Fig. 1 of Enclosure, with the vertical sections showing rms error values, which till 23 June did not exceed 15 km for 5 min of observation (at a deviation of 4 kc) and after 23 June did not exceed 2 km (at a deviation of 32 kc). Measurement error for velocity did not exceed 2.5 cm/sec. Signal propagation time was calculated with an accuracy of  $\pm 5 \mu\text{sec}$ , and Doppler frequency, with an accuracy of  $\pm 0.05 \text{ cps}$ . The total rms error value for the initial data was  $\pm 400 \text{ km}$ .

TITLE: Method for determining statistical characteristics of phase coordinates in  
linear automatic control systems

SOURCE: Avtomatika i telemekhanika, no. 12, 1966, 47-57

TOPIC TAGS: <sup>LINFAH</sup> automatic control system, automatic control R and D, statistic  
analysis, automatic control design, automatic control technology

ABSTRACT: A method of determining mathematical expectation and crosscorrelation  
functions of phase coordinates is set forth; the method is applicable only to linear  
automatic control systems describable by  $\dot{x}(t) = A(t)x(t) + B(t)f(t)$ , with this initial  
condition:  $x(t)|_{t=0} = x_0$ , where  $x(t)$  is the n-dimensional vector of phase coordinates  
(a single-column matrix of phase coordinates);  $A(t)$  is the square, n-th order,  
matrix of coefficients that depends on random design parameters of system  $k_i$ ; with  
 $i = 1, \dots, m$ ;  $f(t)$  is the n-variate vector of external forces;  $B(t)$  is the diagonal  
matrix of coefficients that depends on  $k_i$ ;  $x_0$  is the n-variate vector of initial values

Card 1/2

UDC: 62-501.12

ACC NR: AP7002088

of the phase coordinates. The above system of differential equations is solved for  $t = T$ ; and the solutions have these forms:

mathematical expectation,  $M[x(T)] = \lim_{q \rightarrow \infty} M_q[x(T)]$ ,

crosscorrelation function,  $K_{xx}(T, T_1) = \lim_{q \rightarrow \infty} K_{xxq}(T, T_1)$ .

The number of realizations of random vector  $x(T)$  needed for determining the

mathematical expectation is:  $N = \prod_{i=1}^{n_1} q_i$ , where  $n_1$  - number of design parameters,

$q_i$  - number of realizations of the  $i$ -th design parameter. Thus, the number of  $x(T)$  realizations necessary for determining the mathematical expectation, in the above method, is equal to  $1/q^{n_1}$  the number of such realizations needed in the interpolation method and in the B. G. Dostupov method. With  $n_1 = 10$ , the above method becomes close to the Monte-Carlo method as far as the required amount of calculations is concerned. Orig. art. has: 55 formulas

TITLE: Analytical construction of regulators for two-channel systems with antisymmetric cross couplings

SOURCE: Ref. zh. Kibernetika, Abs. 7G76

REF SOURCE: Tr. Kazansk. aviat. in-ta, vyp. 87, 1965, 66-75

TOPIC TAGS: cross coupling, antisymmetric cross coupling, regulator, regulator design, two channel system

ABSTRACT: The problem of an analytical design for A. M. Letov regulators is generalized for a case of a two-channel system with cross couplings. The equation for the system has the form

$$d(p)x = k(p)u,$$
$$d(p) = p^n + \sum_{a=0}^{n-1} d_a p^a; \quad k(p) = \sum_{b=0}^m k_b p^b, \quad d_a \quad \text{and} \quad k_b$$

are complex numbers;  $x = x_1 + ix_2$  are the controlled coordinates;  $u = u_1 + iu_2$  are the actuation controls. Control  $u_1$  and  $u_2$  are selected from a condition of the functional minimum

Card 1/2

TITLE: Grapho-analytic method for approximate determination of transfer functions from their amplitude-phase characteristics

SOURCE: AN SSSR: Institut avtomatiki i telemekhaniki. Tekhnicheskaya Kibernetika (Technical cybernetics). Moscow, Izd-vo Nauka, 1965, 104-110

TOPIC TAGS: automatic control, automatic control system, transfer function determination

ABSTRACT: A grapho-analytic method is presented for approximate determination of the transfer function of a complex dynamic system on the basis of its attenuation-phase characteristics. This method can be applied to linear systems of minimum-phase as well as of nonminimum-phase types. The transfer function of the dynamic system is taken in the form of a rational fraction for which corresponding attenuation and phase characteristics (logarithmic characteristics)  $A(\omega)$  and  $\phi(\omega)$  as functions of unknown time parameters  $T_1, T_k, T_m, T_s$ , and parameters  $\zeta_s$  and  $\zeta_m$  are written. The problem of determining the transfer function is reduced to determining unknown parameters on the basis of graphs of  $A(\omega)$  and  $\phi(\omega)$ . The basic idea of the method consists in the decomposition of the attenuation characteristic  $A(\omega)$  into characteristics of elementary

Card 1/2

L 17735-66

ACC NR: AT6006214

dynamic components and constructing their asymptotes. The time constants  $T_1$ ,  $T_k$ ,  $T_m$ , and  $T_s$  are determined on the basis of asymptotic attenuation characteristic of the components. To determine the unknowns  $\zeta_s$  and  $\xi_m$ , the system of S + M equations is derived. The sets of parameters  $\{T\}^1$  and  $\{\xi\}^1$  define the first approximation of the transfer function. To obtain more exact values of parameters of the transfer function, the method of successive approximations is applied. An iterative procedure is presented. The method is illustrated by an example in which the transfer function was approximately calculated from given attenuation and phase characteristics of a certain stable dynamic system. It is stressed that this method makes it possible to calculate the transfer function with any desired accuracy and can be applied to systems with delay components. Orig. art. has: 7 formulas.

TITLE: The study of the influence of the porosity of beryllium reflector<sup>19</sup> on the flow of thermal neutrons in horizontal beams

SOURCE: Moscow. Institut atomnoy energii. Doklady, IAE-957, 1965. Issledovaniye vliyaniya skvazhnosti berilliyevogo otrazhatelya na potok teplovykh neutronov v gorizontalykh puchkakh, 1-32

TOPIC TAGS: reactor reflector, neutron beam, neutron flux

ABSTRACT: The intensity of strong neutron fluxes ( $10^{10}$ – $10^{11}$  n/cm<sup>2</sup>.sec) at the exit of experimental reactor beams is in part determined by the flow of thermal neutrons at the header of the beam and by its cross section. In turn, these depend on the properties of the reflector. Since the authors were unable to imitate on the critical stand the active zone with the required spectral composition of the neutrons, they imitated the "thermal" active zone by establishing the appropriate distribution of the thermal neutron flux within the beryllium reflector. This was achieved by placing a 0.5-mm thick cadmium filter between the active zone and the reflector. The present article describes the critical stand used and the methodology of the

TITLE: Diffuse light reflection by a plane semi-infinite almost dispersive atmosphere

SOURCE: Ref. zh. Astronomiya, Abs. 1.51.237

SOURCE: Vestn. Khar'kovsk. un-ta, no. 4, ser. astron., vyp. 1, 1965, 103-107

TOPIC TAGS: atmosphere, light scattering, light reflection, light diffusion, Legendre polynomial, approximation

ABSTRACT: Approximate expressions are obtained for functions in terms of which the intensity of radiation diffusely reflected from a semi-infinite atmosphere is expressed. It is assumed that the scattering indicatrix has the form

$$x(\gamma) = 1 + x_1 P_1(\cos \gamma) + x_2 P_2(\cos \gamma),$$

where  $\gamma$  is the scattering angle;  $P_n(\cos \gamma)$  Legendre polynomials. It is also assumed that the survival of a quantum in the presence of scattering is close to unity. Approximations of the type of Eddington and Schwarzschild-Schuster are used. V. I. [finalization of abstract]

TITLE: Determination of the optical parameters of the planets from observations  
near opposition

19

SOURCE: Ref. zh. Astronomiya, Abs. 11.51.514

REF SOURCE: Vestn. Khar'kovsk. un-ta, no. 4, 1965, ser. astron., vyp. 1, 99-102

TOPIC TAGS: planetary atmosphere, optic measurement, optic property, Jupiter planet

ABSTRACT: It is noted that for small values of planetary phase angle the use of the least squares method to determine the optical parameters of the planetary atmosphere and surface leads to a very poorly specified system of normal equations. A method for determining the optical parameters of the planets from observations near opposition is proposed which, in the author's opinion, allows this difficulty to be overcome. This method is based on the use of dispersion analysis and permits finding the most probable values of the optical parameters and also the greatest number of parameters which can be determined from the observation data. Some results of data analysis of photographic photometry of Jupiter are presented as an example.

The Wind-Power Resources of Voronezhskaya Oblast

The purpose of the work is to clarify the reserves of wind energy in the territory of Voronezhskaya Oblast's. The mean annual velocities of the wind according to a number of stations in Voronezhskaya Oblast are reduced to the altitude 15 meters of a wind gauge, and corrections made for local conditions. The largest number of days with strong wind is observed in January and February, the least in the summer months. The largest number of days with calm is observed in summer. The presented table of mean annual powers of an ideal wind engine, according to data of the meteorological stations of Voronezhskaya Oblast, is computed by means of the formula  $N = 0.000481 D^2 v^3 E_{max}$ , in kilowatts, where  $D$  is the diameter of the wheel,  $v$  is the wind velocity, and  $E_{max}$  is the maximum coefficient of utilization of wind energy of the ideal windmill ( $E_{max} = 0.593$ ). The wind velocities chosen were the mean annual velocities reduced to height 15 meters above the surface of the earth, and corrected for local conditions surrounding the wind gauge. A table of mean annual powers of a wind engine was computed taking into account the frequency of wind velocities from 3 to 10 meters/second according to the formula:  $N =$

0.000481 ( $D^2E/n$ ).( $v_3^3n_3 + \dots + v_{10}^3n_{10}$ ), in kilowatts, where the  $v$ 's are the operating wind velocities from 3 to 10 meters/second, and the  $n$ 's are the frequencies of the velocities corresponding;  $n$  designates the sum of the  $n$ 's. If in the table of the mean annual powers of a wind engine all the data are multiplied by 0.65 (i.e., coefficient 0.38 is used instead of 0.593), then one obtains the power of an actual wind engine. TITLE: Manufacture of Steel From High-P Cast Iron (Proizvodstvo stali iz vysokofosforistogo chuguna)

PERIODICAL: Sb. Mosk. in-t stali, 1957, Vol 37, pp 281-304

ABSTRACT: An analysis of 120 experimental smeltings performed in metallurgical furnaces employing air with 25-30% of O<sub>2</sub>. By employing O<sub>2</sub> the duration of the smelting process is reduced by 8% in the case of silica-brick furnace crowns (SC) and by 33% in the case of furnaces with basic crowns (BC); this reduction in time is accomplished primarily through a foreshortening of the melting and finishing stages. As the content of O<sub>2</sub> is increased from 25 to 30%, the duration of the smelting process diminishes continuously by 6.5-10.7% (in case of SC) and 14-36% (in the case of BC). Introduction of O<sub>2</sub> into the flame, increasing the amount of ore in the upper layers of friable ingredients, smelting procedures which allow slag to remain on the bottom of the hearth - all these measures speed up the processes of slag formation, deposphorization, and

Card 1/2

Manufacture of Steel From High-P Cast Iron

saturation of slag with  $P_2O_5$ . Compared with smelting operations performed without oxygen in furnaces with SC's, the introduction of  $O_2$  into the flame reduced the fuel consumption in furnaces with BC's by 15-18%. Annual output of furnaces employing  $O_2$  increased by 5% in the case of SC furnaces and by 30.8% in the case of BC furnaces in comparison with BC furnaces employing no oxygen. The production cost of steel smelted in BC furnaces employing  $O_2$  is less by 3 rubles than the cost of regular steel. Employment of phosphate slags will reduce the production costs by 17.6 rubles. Additional capital expenditures connected with the employment of  $O_2$  can be recovered within approximately four years.

TITLE: Experiments on the dissemination of precipitating contaminants from a point source in the lower atmosphere

SOURCE: Issledovaniye nizhnego 300-metrovogo sloya atmosfery\*. Moscow, 1963, 3-13

TOPIC TAGS: meteorology, air pollution, precipitating contaminant, point source contamination, lower atmosphere, turbulent diffusion

ABSTRACT: In calculating the diffusion of either precipitating or weightless contaminants in the boundary layer of the atmosphere, a phenomenon which depends both on the properties of the contaminant particles and on the turbulence of the air, the maximum concentration of contaminants and the distance of this point from the source are of considerable interest. The authors therefore present the results of 53 experiments, and derive formulas for these parameters on the basis of 2 systems of calculation, assuming either that the coefficient of vertical turbulent diffusion increases linearly with height, or that it is independent of height. For this purpose, 4 types of atmospheric stratification were distinguished (indifferent stratification and 3 degrees of instability), and inversions were not considered. As shown by graphs relating the height of the source to the dis-

Card 1/2

ACCESSION NR: AT4010218

tance between it and the point of maximum contaminant precipitation, as well as the relationships between atmospheric turbulence and the maximum contaminant concentration or length of the contaminated zone, the distance from the source to the area of maximum contaminant density, corrected for the effect of gravity, was proportional to the height of the source within each type of stratification and within the altitude range of 25-300 meters (error of  $\pm$  25%). The parameters of horizontal diffusion were determined by the type of stratification, while the position and magnitude of the maximum contaminant density and the length of the contaminated zone were determined by the ratio between the gravitational forces and the turbulence. At relatively high turbulence, the first type of calculation yielded better results for the maximum contaminant density, but the second type of calculation was preferable for determining the length of the contaminated zone; at relatively low turbulence, the method of calculation was immaterial. TITLE: A method of investigating the dispersion of an artificial aerosol in the surface layer

SOURCE: Izuchenie pogranichnogo sloya atmosfery s 300-metrovoy meteorologicheskoy bashni. Moscow, 1963, 155-159

TOPIC TAGS: meteorological tower, artificial aerosol, polymethyl methacrylate

ABSTRACT: The 300-meter meteorological tower has been used for an experiment involving the propagation of admixtures in the surface layer. The admixture used was a luminescent polymethyl methacrylate powder, whose advantages were described in the preceding article in the monograph. A special apparatus, illustrated and described in the text, was used for introducing the aerosol into the atmosphere. The apparatus holds 10 kg of powder and can introduce it into the atmosphere at the rate of 0.2 to 2 kilograms per hour. The particles were trapped at distances of 15 to 20 kilometers from the tower. Conclusions are drawn concerning the influence of the underlying surface on the transport of the admixture. Particles were trapped at 50 to 100 stations at distances of 25 meters to 1 kilometer apart. The processing method is described. Orig. art. has: 5 figures.

line region in ethanol and in ethanol-water mixtures.  
N. A. Izmailov and A. M. Aleksandrova. *Zhur. Osnovy Khim.* (J. Gen. Chem.) 19, 1403-15 (1949); cf. C.I. 41,  
1144g.—In MeOH, EtOH, and in mixts. EtOH + H<sub>2</sub>O, 1144g.—In MeOH, EtOH, and in mixts. EtOH + H<sub>2</sub>O,  
the calibration curve of the Hughes and the MacInnes and  
Dole glass electrodes in the alk. region passes through a  
max. With increasing amt. of EtOH, the max. moves to  
more strongly alk. values. In the acid region (HCl), the  
sign of the deviation from linearity between the potential  
and the pH is opposed to that in the alk. region. The  
calibration curve passes through a min. which shifts to less  
acid values with increasing amt. of EtOH. The ion-ex-  
change coeff. K increases from H<sub>2</sub>O to the abs. alcs. Thus,  
from K = 6.31 × 10<sup>-11</sup> in H<sub>2</sub>O, it increases, for the glasses  
of Hughes and of MacInnes and Dole, to 8.0 × 10<sup>-11</sup> and  
2.0 × 10<sup>-11</sup>, resp., in abs. EtOH, and to 2.82 × 10<sup>-11</sup> and  
2.82 × 10<sup>-11</sup>, resp., in abs. MeOH. While the glass elec-  
trode remains perfectly usable in mixts. of EtOH and  
MeOH with H<sub>2</sub>O, the range of its applicability becomes  
narrower with increasing alc. content. N. Thom

Behavior of the glass electrode in the acid region. N. A. Imaikin and A. M. Aleksandrova (A. M. Gor'ki State Univ., Kharkov). Doklady Akad. Nauk S.S.R. 71, 811-13(1953).—The potential  $E$  of a Hughes glass electrode in 3  $N$  and in 5  $N$  HCl and 3-11  $M$  LiCl is a linear function of the activity of the  $\text{Cl}^-$  ions as determined by the e.m.f. in a  $\text{Ag}|\text{AgCl}|\text{Cl}^-$  cell. The same linearity, but with a somewhat different slope, holds in solns. of NaCl in 3  $N$  HCl, and in solns. of  $(\text{NH}_4)_2\text{SO}_4$  of varying concn. in 3  $M$  H<sub>2</sub>SO<sub>4</sub>. Consequently, in the acid region, the glass behaves as a reversible electrode towards the anions, and its  $E$ , at a given low pH, is affected by the concn. of the anions. N. Then

Univ.), Zhur. Otschchet Khim. (J. Gen. Chem., U.S.S.R.)  
30, 2137-38 (1960); cf. C.A. 49, 1430d.—Glass electrodes  
of Hughes (I) and of MacInnes-Dole (II) glass were cal-  
ibrated at pH from 0.3 to -1.4, detd. with the quinhydrone  
electrode (against  $\text{H}_2\text{SO}_4$  0.1437 M in glacial AcOH) in  
the following solns. in glacial AcOH:  $\text{PhNM}_2$  1 M (pH  
8.3);  $\text{AcONa}$  1.0 N (8.1);  $\text{AcONa}$  0.25 N (7.6);  $\text{AcONa}$   
0.1 N (7.38);  $\text{AcONa}$  0.01 N (6.7);  $\text{AcONa}$  0.1 N +  $\text{HClO}_4$   
0.1 N (3.3);  $\text{HClO}_4$  0.05 N (3.4);  $\text{HClO}_4$  0.1 N (2.1);  
 $\text{HClO}_4$  0.3 N (1.4);  $\text{H}_2\text{SO}_4$  0.004 M +  $\text{AcO}^-$  10% (0.3);  
 $\text{H}_2\text{SO}_4$  0.007 M +  $\text{AcO}^-$  10% (-0.3);  $\text{HClO}_4$  0.02 N +  
 $\text{AcO}^-$  10% (-1.4). In aq. soln., electrode I showed a break  
at pH = 0.3, and II a deviation from linearity in the same  
region, but in glacial AcOH both electrodes showed a break  
at pH = 1.3. The potentials  $E$  of both electrodes varied  
linearly with the pH from 1.3 to 2.6, with the slopes  $\Delta E/\Delta \text{pH}$   
= 88.6 for (I) and 88.5 for (II), resp. Consequently,  
both electrodes were applicable for pH measurements in  
that range. Acid hysteresis was absent. Titration of  
 $\text{MeC}_6\text{H}_4\text{SO}_3\text{H}$  with  $\text{PhNM}_2\text{AcOH}$  in glacial AcOH with  
electrode I gave rapid establishment of the potentials (2  
min.) and a sharp peak of  $\Delta E$  against the vol. of reagent  
added.

Electrochemistry

Use of glass electrode in nonaqueous media. N. A. Izmailov and A. M. Aleksandrova. Izdat. Komiitata po Khim. Akad. Nauk S.S.R., Otdel. Khim. Nauk (1954) 140-02(1952); cf. C.A. 46, 4933d.—Over a wide pH interval, 2 electrodes were calibrated for mixts. of H<sub>2</sub>O and O<sub>2</sub>, 20, 71.0, 88.5, 93.5, and 100% EtOH by wt. Also 1 electrode was calibrated for H<sub>2</sub>O, abs. EtOH, and abs. MeOH. The app. is described. The electrodes were sphere shaped, like those of Gaber, but one was made of the glass used by Hughes and the other of the glass used by Maclennan and Dole. The pH of the alc. solns. used was measured by H electrode and compared against a standard, 0.1N HCl in the corresponding soln. Thus, activity was expressed on the scale pH<sub>soln.</sub>. Potentials of the electrode of Hughes glass were plotted against pH. All the curves were similar. In the middle pH range changes were proportional, but a min. occurred somewhere below pH 4 and a max. somewhere above pH 10. In the alk. range a cause of deviation was the differences of the exchange of H ion and Na ion between glass and soln. for different glass compns. For each electrode pH<sub>max.</sub> and K (const. of exchange of ions in glass) were detd. As alc. content increased, K increased because the activity was changed. As alc. content increased, the straight-line portion of the curve was shortened and this was the only limitation on the use of the glass electrode in nonaq. solns. In the middle pH range, pH did not depend on media. When the electrode of Hughes glass was used with H<sub>2</sub>O, abs. EtOH, and abs. MeOH, the differences in curves were explained by differences of phase and diffusion potentials. When the electrode of M. and D. glass was used with H<sub>2</sub>O and 88.5% EtOH, the curves were identical until pH 10, after which point alc. had a max. at a lower point than water had. 25 references. *(Signature)***Behavior of the glass electrode in acids.** N. A. Izmailov  
and A. M. Alekseevskaya [A. M. Gor'ki State Univ., Khar-

kov, Siberian State Univ. Khim., Akad. Nauk S.S.R.]

S.R. 1, 173-B(1953); cl. C.I. 45, 4581d.—To det. the effect of anions on the calibration curve of the glass electrode in acids, measurements were made with a Hughes glass electrode in aq. solns. of HCl, H<sub>2</sub>SO<sub>4</sub>, and H<sub>3</sub>PO<sub>4</sub>. In all acids E vs. pH curves passed through a min., the position of which depended on the anion as well as on the concn. of the acid and the compn. of the glass of the electrode. In HCl at low pH beyond the min., the glass electrode acted irreversibly towards the anion. In H<sub>2</sub>SO<sub>4</sub> at 0.1N, at 0.4 pH (10-16N), at 0.4 pH (25-30N), and in HCl at 0.2 pH (1-2N), E vs. log a ( $a$  = mean activity) in H<sub>2</sub>SO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, and HCl gave min. at log a 0.65, 2.1, and 0.17, respx. E vs. log a<sub>H+</sub> in HCl was a straight line, i.e., there was a straight line almost vertical to the log a<sub>H+</sub> axis down to the lowest E where it became horizontal. At 0.1N there was a wide min. at a high value of E, and since it was concluded that the error of the glass electrode in acids could not be due to the change in the H<sub>3</sub>O<sup>+</sup> activity in the solns., but rather to the likelihood that the electrode in acids acted un un-ion function to the known H<sup>+</sup> function. In acids the electrode beyond the min. acted reversibly towards the anion. — I. Demchuk

ALEKSENDROVICH, D. M.

In the W electrodes and their alloys with Sn, Sb, Bi, Cu, Zn, Cd, As, S, Se, Te, the relation of  $E$  vs. pH did not change with time 0.05%. The value of  $\alpha$  did not change with time, but the abs. values of  $\alpha$  shifted toward the positive side and therefore, a study calibration of W electrodes is recommended in the system of 4-14 pH. The use of W electrodes in the system of 4-14 pH is the best. The use of W electrodes was linear (slope coeff. 0.05), thus it can be used as a glass pH electrode. W electrodes for detg. the pH in nonbuffered solns. (natural waters) did not give satisfactory results. Sb electrodes were used satisfactorily for detg. the pH in the interval of 5-8 in buffered solns. as well as in natural waters. At a pH of 5-8 the Sb electrodes gave more accurate results than did a glass electrode.

TITLE: Detection of chloride ion in muddy and colored ground extracts

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 17, 1962, 132, abstract 17D86 (Pochvovedeniye, no. 2, 1962, 109 - 113 [summary in Eng])

TEXT: In order to determine  $\text{Cl}^-$  in muddy and colored aqueous ground extracts, the methods applied are potentiometric titration of a solution of the sample (0.5 ml 2N  $\text{H}_2\text{SO}_4$  per 10 ml of sample solution) acidified with 0.002N  $\text{AgNO}_3$  solution using an indicating silver chloride electrode (Pt-wire, covered with a mixed paste of  $\text{Ag}_2\text{O}$  and  $\text{AgCl}$  (7:1) and calcined at  $450^\circ\text{C}$ ); and visual mercurimetric titration with diphenyl carbazole as indicator in the presence of benzene. To 10 ml of the sample solution, 10 ml of water and then a few drops of 1% solution of diphenyl carbazole are added, neutralized with a 0.2N  $\text{HNO}_3$  solution (till yellow color), 5 ml of benzene is added and the mixture titrated with a 0.01N  $\text{Hg}(\text{NO}_3)_2$ .

## TITLE:

An Accelerated Method for the Determination of Germanium in  
the Ashes of Coal Minerals (Uskorennyy metod opredeleniya  
germaniya v zole iskopayemykh ugley)

## PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 2, p 161 (USSR)

## ABSTRACT:

In the method described the coal sample is fused by heating in phosphoric acid and treated with hydrochloric acid; then the germanium chloride which has formed is distilled off and the germanium is determined colorimetrically with phenol fluorone. In comparison with the analogous analysis of ores by Strickland (Ref 1) twice as much phosphoric acid and no nitric acid is used in the present case. Coal samples (brown coal, types D, G, PZh, K, and PS) were determined by the method described and at the same time by a method in which the decomposition was performed in a mixture of hydrofluoric acid and sulfuric acid. A comparison (Table) of the results showed a remarkable agreement. In the presence of larger quantities of chlorides (more than 10%) losses of germanium may occur in the fusion process, as was shown by I. P. Alimarin and B. N. Ivanov-Emin (Ref 2) in the case of the hydrofluoric acid - sulfuric acid mixture. Duration of analysis by the method described:

TITLE: Selection of coal ashing conditions for germanium determination

52

SOURCE: Zavodskaya laboratoriya, v. 29, no. 7, 1963, 797-799

TOPIC TAGS: germanium, germanium determination, ashing, coal ashing, ashing temperature, heating rate, ash content, Ge

ABSTRACT: The behavior of germanium during the process of ashing of various coal samples was investigated in relation to the rate of temperature increase, the amount of mineral admixtures, the total sulfur content of the coal, and the ashing temperature. Five-gram samples of coal were placed in a furnace, the temperature raised at rates of 3.5 and 200 per minute until a final temperature of 550°C was reached, at which the ashing was continued until completed. The ash was analyzed for germanium, and it was found that in a brown coal sample with 13.41% ash the loss of germanium at a 3.50-increase rate amounted to 2.3% of its original content, while at an increase rate of 200 per minute the germanium loss amounted to 10.0%. On the other hand, a furnace-type bituminous coal with a 4.46% ash content lost (under identical ashing conditions) 2.7% and 6.7% respectively of the original germanium content. In

Card 1/2

L 15668-63

ACCESSION NR: AP3004220

order to check the effect of ash on the loss of germanium during the ashing process, each sample was separated into two fractions by difference in specific gravity, the one floating on top of a nonspecified fluid, the other settling. The ash content of the floating fractions of the same brown and bituminous coal samples amounted to 2.54% and 1.35% respectively, as against 26.17% and 38.81% in the settling fraction. After ashing at the 3.5C-rate, the losses of germanium amounted to 0.4% and 8.1% in the floating fractions, as against 2.5% and 0.0 in the settling fractions, thus placing emphasis on the kind of coal being ashed. The recommended procedure for the ashing of coal samples for germanium determination consists in a staggered increase of temperature at a rate of 3.5C per minute, with a maximum of 700C-800C, and duration of 3.5-4 hours. Orig. art. has: 2 tables.

PURPOSE: This book is intended for scientists and researchers in  
the field of spectroscopy, as well as for technical personnel  
using spectrum analysis in various industries.

COVERAGE: This volume contains 177 scientific and technical studies  
of atomic spectroscopy presented at the 10th All-Union Conference  
on Spectroscopy in 1956. These were carried out by  
members of scientific and technical institutes and include  
extensive bibliographies of Soviet and other sources. The  
studies cover many phases of spectroscopy: spectra of rare earths,  
uranium production, physicochemical methods for controlling  
optical dispersion, theory, spectrum analysis of ores  
and minerals, photographic methods for quantitative spectrum  
analysis of metals and alloys, spectral determination of  
hydrogen content of metals by means of isotopes, tables, and  
atlasses of spectral lines, spark spectrographic analysis,  
statistical study of variation in the parameters of calibration  
curves, determination of traces of metals, spectrum analysis in  
metallurgy, thermochrometry in metallurgy, and principles and  
practice of spectrochemical analysis.

TOPIC TAGS: high-melting metal, electron vacuum device, machining, tungsten powder, molybdenum powder, wire, rolling, laminating, electron-beam melting

PURPOSE AND COVERAGE: This booklet describes the equipment for chemical and thermal treatment and machining refractory metals used in the manufacture of electron vacuum devices. The book is intended as a text for the section of the course "Mechanical Equipment in the Manufacture of Electron Vacuum Devices" on equipment. It can also serve as a text for students in similar specialties and can be useful to engineers, technicians, and workers engaged in the production of refractory metals.
