An Apparatus for Measuring the Intensity Distribution in an Expanded γ -ray Pulse from a Synchrotron

the time scale either by hand using a time delay circuit, or the whole pulse is split into n sections and the instrument automatically covers the whole time interval using a step-by-step switch. The circuits of the two channels are shown in Fig 2 and the time delay circuit is shown in Fig 3. The step-by-step switch is shown in Fig 4. The apparatus has been used in studying elastic scattering of γ quanta on protons (Ref 4), photo-production of π^0 -mesons (Ref 3) and electron distributions associated with radial-phase oscillations. There are 4 figures and 4 Soviet references.

TITLE: All-Union Intercollege Conference on Electron Accelerators

PERIODICAL: Atomnaya energiya, 1960, Vol 8, Nr 3, pp 268-269 (USSR)

ABSTRACT: The conference, in which scientists from universities, colleges, scientific research institutes, and industry took part, was held in September 1959 in Tomsk and discussed theoretical and technical matters, control, stabilization, and accessories to electron accelerators, and their application in metallurgy, machine construction, geology, geophysics, and medicine. The transactions of the conference are scheduled for publication by the Tomsk Polytechnic Institute (Tomskiy politekhnicheskii institut).

TITLE: Bremsstrahlung spectrum of 260-Mev electrons

PERIODICAL: Atomnaya energiya, v. 12, no. 3, 1962, 193 - 197

TEXT: The bremsstrahlung spectrum of 260-Mev electrons from the synchrotron of the FIAN was measured on a simple arrangement with a 15-channel gamma pair spectrometer of a total dispersion of $3.3 \cdot 10^{-2}$. The efficiency of gamma-quantum recording was $8.25 \cdot 10^{-6}$, radiation intensity was equal to $1.2 \cdot 10^7$ Mev/cm²·sec. Experimental error was 5%. The experimental results were compared with the calculated number of photons $N^l(t, k)$ of energy k at a depth t in the target, which in first approximation (error 2 - 3%) is

$$N^r(t, k) \approx N_r(0, E_0) \sigma_r(t, E_0) e^{-at} \left\{ 1 + \right. \\ \left. + t \left[0.6a - 0.305 + 0.722 f_1(\eta) + \right. \right. \\ \left. \left. + 0.722 \frac{a}{k} \left(\left(1 + \ln \frac{E_0}{k} \right) \ln \ln \frac{E_0}{k} + 1 \right) \right] \right\}. \quad (3)$$

$$f_1(\eta) = \int_0^\eta \ln \xi e^{-k\xi} d\xi$$

The bremsstrahlung cross section $\sigma_T(E, k) \approx 1/k$; $\eta = \ln(E_0/k)$; $n_0^r(t, \eta)$

$= \int_0^t e^{-at'} W(t', \eta) dt'$. E_0 is the energy of the primary electrons. When

multiple photon emission is taken into account, agreement between theory and experiment is improved. The spectrum distortion owing to the collimator effect does not exceed 2%. The material (foil, air, window) through which the gamma ray passes has an influence on the spectrum only in the low-energy range. The discrepancy between experiment and Schiff's theory (Phys. Rev., 83, 252 (1951)) is due to multiple phonon emission from one electron. Professor P. A. Cherenkov is thanked for discussions, Engineer M. P. Piskov and Technician Yu. I. Krutov for help. TITLE: A 6.5 Mev microtron for electron injection into a synchrotron

PERIODICAL: Atomnaya energiya, v. 14, no. 4, 1963, 359 - 363

TEXT: It is first pointed out that the relatively high intensity of the electron beam attained in conventional microtrons, the simple design of the device, the escape of a relatively large amount of electrons from the accelerator, the great similarity of the electron energies, the small divergence angle of the electrons, and other facts indicate that the microtron may also serve as a synchrotron injector. These assumptions were checked by the authors on the 280 Mev synchrotron of the Fizicheskiy institut im. P.N. Lebedeva AN SSSR (Institute of Physics imeni P.N. Lebedev, AS USSR) with the aid of their 6.5 Mev microtron. The number of electrons retained during acceleration when a magnetron is used as a synchrotron injector is estimated at about $2.5 \cdot 10^{10}$. It is thus proved that modern accelerators of this type are very efficient already now, and further de-

TITLE: On new possibilities of increasing the efficiency of a microtron ¹⁹

SOURCE: Atomnaya energiya, v. 15, no. 1, 1963, 62

TOPIC TAGS: microtron, ferrite isolator, magnetron, automatic bias

ABSTRACT: A ferrite isolator, serving as a matching and decoupling element between a magnetron oscillator and an accelerating resonator was substituted for the conventional water-load system and the phase shifter in a microtron. As a result of this improvement, the power loss in the microtron waveguide was reduced, microtron efficiency was increased by a factor of approximately two and the stability of the h-f channel was increased markedly due to decoupling between the magnetron oscillator and the load. Through reduction of waveguide length and the number of joints in the waveguide it was possible to make the system hermetic, thus increasing considerably its electric strength. Since the ferrite isolator functions simultaneously as a matching element, attenuator, and phase shifter, the adjustment procedure and control of the microtron were considerably simplified.

Card 1/2

L 11297-63
ACCESSION NR: AP3003978

A further increase in efficiency can be obtained by increasing coefficient k , which is the ratio of the number of electrons in the beam to the number of injected electrons. The k can be increased by applying a positive bias to the microtron injected cathode. Smooth adjustment of the bias is effected by changing the internal resistance of the high-voltage triode located between the microtron cathode and the ground. It was shown in experiments, that k is a linear function of the positive bias in the first approximation. The value of the linearity coefficient depends on the dimensions of the resonator injector aperture and on the location of the cathode. Thus, it was possible to increase k by 10% at a positive bias of approximately 2-3 kv, and to increase the pulsed current of accelerated electrons in the microtron up to approximately 110 mamp at an energy of 6.5 Mev. TITLE: The possibility of generating and accelerating positrons in a microtron

SOURCE: Atomnaya energiya, v. 16, no. 4, 1964, 353-354

TOPIC TAGS: positron, microtron, gamma radiation, storing device, electron positron beam, bremsstrahlung, electron positron pair, relativistic positron, annihilation radiation, electron cyclotron

ABSTRACT: The use of a microtron is proposed for the production of accelerated positrons. The latest achievements in the development of highly efficient microtrons justify the hope that the proposed method will facilitate production of much more intensive positron beams, compared to those in current production, and reduced overall equipment costs. Under the new scheme, the electrons emitted from an injector are accelerated by the electric field of a high-frequency resonator to the maximum energy level achievable in the given

Card 1/2

ACCESSION NR: AP4029697

microtron. In view of the high intensity of the high-frequency electric field ($E \approx 380$ kv/cm), a considerable portion of the positrons with an initial energy of about zero will be captured by the microtron acceleration system. A further acceleration of the positrons occurs simultaneously with the following bunches of electrons, and most of the orbits coincide spatially. In their last orbit the positrons are automatically deflected by a system of magnetic canals, and can be removed from the microtron for the purpose of generating monochromatic annihilation gamma-radiation or for accelerating to higher energy levels. The above outlined method of generating and accelerating positrons was experimentally tested at the photomeson laboratory of the SSSR Academy of Sciences. Orig. art. has: 1 figure and 1 formula.

TITLE: Storage of particles in a synchrotron 19

SOURCE: International Conference on High Energy Accelerators. Dubna, 1963. Trudy.
Moscow, Atomizdat, 1964, 355-357

TOPIC TAGS: high energy accelerator, charged particle beam, particle physics,
synchrotron

ABSTRACT: Synchrotron-type accelerators of several 100 Mev and higher can be employed for particle storage [Yu. M. Ado, "Atomnaya Energiya, 12, 54 (1962)]. In the case of simultaneous storage of electrons and positrons in an accelerator, one can obtain colliding electron-positron beams. In order for a synchrotron to operate in the storage state, the constant component of the driving magnetic field must be larger than the amplitude of the variable component. In particular, if the variable component is a sinusoidal function of time, the driving magnetic field H must have a specified shape. In this case, the accelerating hf potential is step-shaped.

Card 1/4

L 46158-65

ACCESSION NR: AT5007923

i.e. remains switched on continuously in contrast to the synchrotron's operation in the usual state. The injection of particles is effected at moments of time t_1, t_2, t_3, \dots , which correspond to intersections of the ascending curve H -versus- t with the constant ordinate H_1 . The particles captured in the synchrotron state of the storage device, which are accelerated during the rising portion of the magnetic field H and slowed down when the magnetic field is decreasing, remain in the accelerator chamber for a period that is determined mainly by the scattering processes and by the bremsstrahlung on the atoms of the residual gas. During each period of the driving magnetic field H close to maximum H there exists considerable radiation damping of the amplitudes of betatron and synchrotron oscillations. As a result, the phase volume occupied by the particles decreases. This permits the onset of amplitude modulation of the specified hf-potential without loss of the particles captured earlier. In this case, the injection of particles will proceed into the phase space between the separatrices which are defined by the amplitudes of hf-potential U (maximum step value) and $U - \Delta U$ (modulation decrement due to H being less than H_1 for the brief periods just before t_1, t_2, t_3, \dots). The admissible depth of modulation ΔH is larger the larger the magnitude of radiation damping of the oscillations. The effectiveness of the injection into the synchrotron state of storage during onset of amplitude modulation of the hf-potential is ten times the effectiveness of injection directly into the steady-state separatrix. In the case

Card 2/4

L 16158-65

ACCESSION NR: AT5007923

of particle storage in a synchrotron, injection is effected into the variable magnetic field during the low energy of the injected particles which is typical for the given accelerator. Consequently the problem of particle injection is essentially simplified in comparison with injection into storage rings. Moreover, the small injection energy simplifies the problem of obtaining positrons. These properties permit attainment of a comparatively high rate of storage and thus a lowering of the requirements made on the degree of vacuum. To verify the possibility in principle of realizing the method of particle storage in a synchrotron, experiments were carried out on a 280-Mev synchrotron under specific conditions of particle energy (170 Mev for maximum H and 7 Mev for minimum H), amplitude U , of hf-potential (1.8 kv), modulation depth ΔU (0.36 kv), rate of growth of driving magnetic field at moment of injection ($1.5 \cdot 10^5$ oersteds/sec), pressure of residual gas in vacuum chamber ($5 \cdot 10^{-6}$ mm/Hg). The source of electrons is an 8-Mev microtron [K. A. Belovintsev, A. Ya. Belyak, A. M. Gromov, Ye. M. Moroz, P. A. Cherenkov, "Atomnaya Energiya, 14, 359 (1963)]. Finally as shown by tests conducted on electron storage in a synchrotron, it is possible to carry out simultaneous storage of both electrons and positrons in quantities sufficient for setting up experiments on colliding beams if the pressure in the vacuum chamber is lowered to 10^{-8} mm/Hg and the conditions for particle capture are suitably improved. Orig. art. has 4 figures.

TITLE: A positron microtron

SOURCE: AN SSSR. Mikrotron (Microtron); sbornik statey, 1944-1965 gg. Moscow, VINITI, 1965, 118-125

TOPIC TAGS: particle accelerator, electron accelerator, positron, synchrotron

ABSTRACT: The authors consider the possibility of using a microtron as a general-purpose injector for a synchrotron storage ring. Methods for producing, accelerating, and extracting positrons from the microtron are discussed. If a beam of electrons from the last orbit is directed at the positron converter K located on the wall of resonator P of the microtron (see Fig. 1), the angular coefficient for capture of positrons leaving the converter with low energies will be considerably higher than in the case of direct conversion on the storage ring target due to the high electric field strength in the resonator (about 400 kv/cm). Spatial displacement of the electron beam toward the converter is accomplished by using two magnetic channels l_1 and l_2 with a difference in length which determines the amount of displacement ΔL . An approximate expression is given for determining the length of the magnetic channels.

Card 1/2

L 28820-66

ACC NR: AT6013168

Diagrams are given showing the regions of positron capture for various initial velocities and phases in the horizontal and vertical planes. The proposed method for positron acceleration was checked out on the microtron at the photomeson laboratory in the Physics Institute im. P. N. Lebedev AN SSSR with an electron-to-positron beam conversion coefficient of 10^{-5} to 10^{-6} . Experimental work on improving the method is still in progress. A second method is proposed for positron emission in a microtron where the converter is placed at the edge of the resonator opening. Insufficient data on the important parameters which characterize this method make it difficult to compare it with the first method. A design is proposed for a universal microtron injector with two electron injectors and a positron converter. This system uses a single magnetic channel for simultaneously directing the electron beam to the converter and deflecting the positron beam. The installation may be easily adjusted for production of two electron beams when necessary. Orig. art. has: 4 figures. [14]

Fission of U by negative pi-mesons

FD-2349

Card 1/2 Pub. 146 - 14/34

Author : Belovitskiy, G. Ye.; Romanova, T. A.; Sukhov, L. V.; and Frank,
 I. M.

Title : Fission of uranium nuclei under the action of slow negative pi-
 mesons and high-energy particles

Periodical : Zhur. eksp. i teor. fiz. 28, 729-732, Jun 1955

Abstract : In this work the authors investigate the fission of uranium nuclei
 by slow negative pi-mesons (G. Ye. Belovitskiy, et alii, Otchet
 FIAN*, April 1950, June 1950, March 1951), by fast neutrons, with ener-
 gies up to 460 Mev, and by gamma-rays with energies up to 250 Mev
 (G. Ye. Belovitskiy et alii, ibid., Dec. 1952). For the recording
 of the fission of uranium nuclei they used photoplates with
 emulsion layer 100 microns thick with uranyl acetate (T. A.
 Romanova and G. Ye. Belovitskiy, ibid., June 1951), which plates
 permitted the observation of protons with energies up to 30 Mev.
 The irradiation of the plates by slow negative pi-mesons and fast
 neutrons was carried out in the synchrocyclotron of the Institute
 of Nuclear Problems. Academy of Sciences USSR; the irradiation by
 gamma-rays was by the synchrotron of FIAN*. They note that the
 energy spectrum of neutrons from "overcharging" (peresaryadka) of

Card 2/2

FD-2349

670-Mev protons on beryllium was measured by V. B. Flyagin. They present 5 photographs of indicated fission. They thank Prof. M. G. Meshcheryakov, G. P. Dzheleпов, and Ye. Grigor'yev for aid in experiments with negative pi-mesons and fast neutrons, and also thank Prof. V. I. Veksler and Yu. S. Ivanov for aid in experiments with gamma-rays of high energy. They state that a more detailed report on the results obtained will be published in this journal. They conclude that the distinguishing peculiarity of the process of fission of uranium nuclei at high energies of excitation is the significant probability of the emission of fast protons and alphaparticles; these particles bear only a comparatively small part of energy obtained by the uranium nucleus from the primary particle. Thirteen references.

Title : Fission of uranium nuclei under action of slow π^- mesons, fast neutrons and γ -rays up to 250 Mev energy

Periodical : Zhur. Eksp. i Teor. Fiz., 29, No 5 (11), 537-550, 1955

Abstract : Fission of U-nuclei by slow π^- mesons, fast neutrons and high energy γ -rays was studied on thick emulsion photographic plates. The probability of U-nuclei fission at π^- capture proved to be high. It is evaluated around 0.5. Under high excitation energy the fission is probably accompanied by charged particles emission, i.e. protons and α particles. Energy spectra and angular distributions of particles were obtained and plotted. These data were used for discussion of the mechanism of U nuclei fission at high excitation energy. Title : Spring Stage for Measuring Multiple Scattering of
Particles in a Photographic Emulsion.

Orig Pub : Pribory i tekhn. eksperimenta, 1956, No 1, 162-165.

Abstract : Description of the construction of a spring stage, having
very low noise level (~ 0.01 -- 0.03μ). The noise
measurement occurring during vertical displacement of
the objective is carried out, as is the measurement of
thermal noise due to non-uniform heating of various parts
of the microscope. Steps that permit substantial reduc-
tion of the thermal noise are proposed.

TITLE:

Inelastic Scattering of Positive and Negative π -Mesons With Energies of 300 MeV on the Nuclei of Photoemulsions
(Neuprugoye rasseyaniye polozhitel'nykh i otritsatel'nykh π -mezonov s energiyey 300 MeV na yadrakh fotoemul'siy)

PERIODICAL:

Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1958,
Vol 35, Nr 4, pp 838-844 (USSR)

ABSTRACT:

The author reports on investigations of the inelastic scattering of 300 ± 15 MeV π^- and π^+ mesons on emulsion nuclei. He uses photographic plates of the types NIKFI and Ilford G-5 (400μ). The number of nuclei per cm^3 of the first-mentioned type (without hydrogen) is $\sim 7.5 \cdot 10^{22}$. In the following, the results obtained by the analysis of 5000 "stars" are published. 1. Determination of the inelastic scattering cross section (Ref 8). Investigations were carried out of: π^- :1622-stars, π^+ :1377-stars on NIKFI, further of 286 π^- -stars on G-5; rate of percentage of cases of inelastic scattering: π^- :(45 ± 2)%, π^+ :(40 ± 2)% (NIKFI) and π^- :(38 ± 4)% in (G-5);

Card 1/3

Inelastic Scattering of Positive and Negative π -Mesons With Energies of 300 MeV on the Nuclei of Photoemulsions SOV/56-35-4-2/52

inelastic scattering cross sections: π^- : 200 ± 32 mb ,
 π^+ : 185 ± 33 mb.

2. Angular distribution in inelastic π^- - and π^+ -scattering. Two measurement series: $E > 60$ MeV - (Fig 1) and $E > 10$ MeV (Fig 2). Ratio of the number of mesons with a scattering angle of $< 90^\circ$ (and $> 90^\circ$) (the values for $\angle > 90^\circ$ are in brackets) :

π^+ : 1.48 ± 0.14 (1.5 ± 0.33); π^- : 1.15 ± 0.1 (1.19 ± 0.23)

3. The energy spectrum of inelastically scattered π^+ - and π^- -mesons (Fig 3). For π^- the maximum is about 50 - 100 MeV, for π^+ it is shifted towards higher energies.

Average energy values:

	0 - 60°	60 - 120°	120 - 180°	(scattering angle)
π^+ -300 MeV	186	163	152	
π^- -300 MeV	194	103	95	

4. Determination of the cross section of exchange scattering:

Card 2/3

Inelastic Scattering of Positive and Negative π -Mesons With Energies of 300 MeV on the Nuclei of Photoemulsions SOV/56-35-4-2/52

In the course of the investigation of 5000 stars 3 electron pairs were found which originated from the decay:

$$\pi^0 \rightarrow e^+ + e^- + \gamma, \text{ with the cross section}$$

$$\sigma_{\pi^+ \rightarrow \pi^0} \approx \left(\frac{3.80}{5000}\right) \cdot 450 \approx (20 \pm 12) \text{ mb}.$$

In the 5th and last chapter results are discussed. The author thanks I. M. Frank for his advice, and A. P. Lager and O. N. Pavlova for their help in carrying out measurements. There are 4 figures, 1 table, and 14 references, 7 of which are Soviet.

TITLE: An Apparatus for the Automatic Measurement of Multiple
Scattering of Particles (Ustanovka dlya avtomatizatsii
izmereniy mnogokratnogo rasseyaniya chastits)

PERIODICAL: Pribory i tekhnika eksperimenta, 1959, Nr 2,
pp 86-90 (USSR)

ABSTRACT: The instrument may be used to carry out both measuring
and computing operations on multiple Coulomb scattering.
It can also be used to measure lengths. The table of
the microscope can be moved repeatedly through fixed
intervals (50, 100, 250 and 500 μ). The second
coordinate which gives the deviation of the track from
the x-axis is transformed into electrical pulses by means
of a photoelectric device in the micrometer eyepiece.
These pulses are transmitted to the computing part of the
apparatus and the number of pulses given by the photo-
electric device in each measurement of the y-coordinate
is proportional to the magnitude of the first difference
in the coordinates. The instrument is not fully
automatic since an observer must place the track manually
in a standard position. The apparatus was checked

Card 1/2

of Particles

against an observer and the average percentage difference between the semi-automatic machine and an observer working with an ordinary microscope is 1-5%. The use of this machine cuts down the scanning time by a factor of 5 and increases the accuracy because it eliminates any possible arithmetical errors committed by the observer. The instrument can also be used with bubble chambers and Wilson cloud chambers. A.V. Shileiko and M.I. Tret'yakova are thanked for their help.

AUTHOR: Belovitskiy, G. Ye.

TITLE: Application of the "Z-Law" by Fermi and Teller to a Photoemulsion Containing Uranium

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960, Vol. 38, No. 2, pp. 658-660

TEXT: It has been found that, contrary to Fermi's and Teller's theoretical predictions, the relative capture probability of slow μ^- -mesons by various atoms in chemical compounds is not proportional to Z, but depends on the number of atoms of the respective element in the molecule of the compound. Calculations of the uranium-fission probability P_f have

usually been based on the assumption that the Z-law holds for the pion-capture probability of various atoms in the gelatin of the photoemulsion. In the present "Letter to the Editor" the writer studies the question as to what extent this assumption is justified. The writer intends to verify values of P_f so far obtained (P_f was between 0.18 and 0.5), for

which purpose repeated experiments were made on uranium fission by slow π^- -mesons. Nuclear emulsion plates of the type $\text{HMK}\Phi\text{M}-\text{P}$ (NIKFI-R)²⁸ impregnated with uranyl acetate were used (200 μ thick). The uranium nuclei contained in the layer were determined by alpha-counting. The plates were bombarded with a beam of slow π^- -mesons on the synchrocyclotron of the OIYaI (Joint Institute of Nuclear Research); the μ^- -admixture was 20%, the portion of fissions released by them was 3% and is taken into account. Experimental data are compiled in a table. Calculations of P_f based on the following assumptions: 1) U is completely adsorbed on gelatin (according to O. V. Lozhkin and V. P. Shamov); 2) the π^- -capture probability of the various elements in gelatin is calculated (except for hydrogen) in which a) the π^- -capture is proportional to Z, and b) the π^- -capture is proportional to the number of atoms of the respective element in gelatin. In the first case $P_f \approx 0.4$, in the second $P_f \approx 6$. The second case was neglected with regard to gelatin + uranium investigation. An experiment on Th^{232} fission by 10- to 340-Mev protons revealed that P_f rapidly increased

Card 2/3

Application of the "Z-Law" by Fermi and Teller

with energy, attains 0.45 ± 0.07 at ~ 50 Mev, after which it remains constant. Also $P_f(\text{Pa}^{238})$ was equal to ≤ 0.45 . $0.35 < P_f \leq 0.45$ resulted for excitation energies of 25-45 Mev. When $P_f \approx 0.35$, the capture probability is proportional to Z^n with $n = 1.25$. Thus, it may be assumed for the gelatin-uranium medium that the capture probability is proportional to Z rather than to the number of atoms. There are 1 table and 7 references: 2 Soviet, 2 Italian, and 3 American.

Drashalkova, A. V. PRODUCTION OF MAGNESITE BRICK
BY THE WATER-VAPOR TREATING METHOD. *Ogneupory*, 3
[11] 811-24 (1933).—High-quality brick may be obtained
by hydration of the active oxides of calcium and magne-
sium with steam. By this method, brick with a higher
lime content (up to 5%) are obtained. The steam treat-
ment promotes the formation of a more homogeneous mix
with respect to moisture and degree of hydration.

Microfilm frame containing a document page. The page features a large handwritten letter 'A' in the top left corner. The main text is a technical report in Russian, discussing the spalling of magnesite brick. The text is as follows:

Табеев, З. Я., Болородкин, В. В., and Тардиков, О.
МАГНЕЗИТОВАЯ КИРПИЧНАЯ СТЕНКА ОТ СПАЛЛИНГА. *Ogneupory*,
6, 110-12 (1930).—Extensive investigations have been
carried out in Russia on the application of various types of
brick in large open-hearth furnaces. The best results were
obtained by using magnesite brick and these resisted spall-
ing well. The magnesite contained about 90% magnesia.
Fusing with quartzite produced the spinel product which
was resistant to spalling and deformation under a 2 kg./cm.
load taking place at 1680°C.

The form includes various labels and markings, such as 'COMMON VARIABLES INDEX' on the left and 'COMMON LIBRARY' on the right. At the top and bottom of the frame, there are rows of alphanumeric characters and numbers, likely representing the microfilm's track or frame numbers.

TITLE: Firing from a moving tank

SOURCE: Voyenny vestnik, no. 5, 1966, 113-114

TOPIC TAGS: military tank, conventional warfare, gun sight

ABSTRACT: The estimation and selection of lead angles and time lags for aiming and firing from a moving tank is discussed with reference made to an article by Colonel Yu. Semenov published in "Voyenny vestnik", no. 12, 1965. Colonel Semenov proposes that the lead taken be always equal to $1/3$ of the sight mark swing or $2/3$ of the amplitude. Approving this proposal, the author, however, thinks that such a method can be successfully used only on condition that the oscillation period is equal to one second, with the proper time lag of 0.16 sec. This lag of 0.15 to 0.16 sec is stipulated in the firing rules. In the author's opinion, such a quick response can be demonstrated only by well trained and experienced gunners. In general, the firing practice shows that the time lag lies within the limits of 0.15 to 0.25 sec. Consequently, the author presents the results of his calculations of the lead based on the time lag of 0.2 and 0.25 sec and various pitching movements of the tank. The calculations were made for various target heights

Card 1/2

ACC NR: AP6027118

varying from 1 to 3 m. The results, summarized in a table, are analyzed and recommendations for firing are presented. In general, it is concluded that a greater lead is needed for a smaller target and a greater range as well as for an extended time lag and a higher angular velocity of the tank pitching movement. The importance of training for acquiring needed standards and habits for firing while moving is stressed. Orig. art. has: 1 table.

Development of Extraction of Bituminous Shales.
 (In Russian.) V. T. Belovkov. *Ugol (Coal)*, v. 25, Aug. 1950, p. 24-25.

Reviews developments of the past 10 years, especially the postwar years, in extraction and utilization of bituminous shale. Such shale is said to be widely used in the U.S.S.R. as a source of solid fuel and fuel gas, and as a raw material for production of chemicals, replacing petroleum to a large extent. Preparatory work had already been done in Esthonian S.S.R. and the Leningrad region, as well as in the Kubyshov and Saratov regions. At the end of 1948, a new gas-producing plant was in operation in the Leningrad region.
