Some Exact Solutions of the Equations of
Compatibility for the Components of the Deform-
ation Tensor Under Simple Load

S/020/60/130/06/011/059
B013/B007

first indices are linearly interdependent. If ψ_{11} , ψ_{22} , ψ_{33} are chosen as arbitrary functions, one obtains $\psi_{12} = a\psi_{11}$, $\psi_{13} = b\psi_{11}$; $\psi_{21} = \frac{1}{a}\psi_{22}$, $\psi_{23} = \frac{b}{a}\psi_{22}$; $\psi_{31} = \frac{1}{b}\psi_{33}$, $\psi_{32} = \frac{a}{b}\psi_{33}$, where a and b are arbitrary constants. This corresponds to the following values of the components of the tensor of finite deformation (with arbitrary ε_{11} , ε_{22} , ε_{33}): $\varepsilon_{12} = \frac{1}{2}(a\varepsilon_{11} + \frac{1}{a}\varepsilon_{22})$, $\varepsilon_{13} = \frac{1}{2}(b\varepsilon_{11} + \frac{1}{b}\varepsilon_{33})$, $\varepsilon_{23} = \frac{1}{2}(\frac{b}{a}\varepsilon_{22} + \frac{a}{b}\varepsilon_{33})$. There are 2 Soviet references.

TITLE: On the possibility of considering the stress-strain state of a medium as the initial state

PERIODICAL: Prikladnaya matematika i mekhanika, v. 27, no. 1, 1963, 135-141

TEXT: Using tensor methods, the author investigates the mathematical consequences of considering a medium as a second initial state. A number of conclusions are drawn as to when certain terms (corresponding to physical phenomena) may be ignored: it is shown, for example that when the displacements and their two first derivatives with respect to the coordinates are all small, that the dependence of the massive force on the stress may be ignored. A brief discussion is given of an elastic-plastic medium, based on the postulate of D.G. Drucker.

TITLE: Three-Electrode Automatic Welding of Fillet and Groove
Welds under Powder Flux

PERIODICAL: Avtomaticheskaya svarka, 1959, Nr 9, pp 3-12 (USSR)

ABSTRACT: In large serial production of structures with long
welds, such as beams, columns, tubes, wings, etc., the
speeding-up of the welding process plays an important
role. This impelled the Institute of Electric Welding
imeni Ye.O. Paton, to carry out systematic research
on welding under forced conditions. In 1946-1948, the
Institute worked out the process of automatic welding
under powder flux permitting making the longitudinal
groove welds at a speed of 100-120 m/hour. Later on,
the process of double-arc welding was introduced and
raised the welding efficiency up to 150 m/hour. In

Card 1/3

SOV/125-59-9-1/16

Three-Electrode Automatic Welding of Fillet and Groove Welds under Powder Flux

1955-1956, research on technology of three-electrode automatic welding of large-section double-T beams was conducted. On the basis of experiments, it was determined that groove welding of beams having wallsides 8-20 mm thick, (Fig 1), can be accomplished by the three-electrode method at a speed of 100-180 m an hour. Three-electrode welding can be performed using a 3-6 mm electrode wire; for this purpose both direct and alternating current can be applied. Welding with the first electrode provides good results independently of whether its current differs from that of the other two arcs. The first arc heats the edges to be welded, the second and the third increase the depth and width of fusing; combined action of all three electrodes permits welding at high speeds, which are unattainable when other methods of arc welding are used. Tables 1 and 2 give specific conditions of welding for two-sided groove-welds. The three-electrode process enables

Card 2/3

SOV/125-59-9-1/16

Three-Electrode Automatic Welding of Fillet and Groove Welds under Powder Flux

performing of high quality fillet welds at a speed up to 100 m/hour, provided the carbon content in welds is under 0.13%; the groove welding speed can be brought up to 180 m/hour. Automatic three-electrode welding is a variety of three-phase welding and possesses all the advantages of the latter. Chemical composition of the weld metal and its mechanical properties can be regulated within broad limits by using electrodes of different makes and diameters. There are 4 graphs, 10 tables 3 diagrams and 5 references, 4 of which are Soviet and 1 German.

TITLE: Dependence of the piezoresistance of germanium on the electric field

SOURCE: Fizika tverdogo tela, v. 8, no. 4, 1966, 1188-1192

TOPIC TAGS: germanium, single crystal, piezoelectric property, carrier scattering, pressure effect, electric field, semiconductor band structure

ABSTRACT: The purpose of the investigation was to check experimentally, in the case of germanium, a hypothesis advanced in an earlier paper (Phys. St. Sol. v. 11, 255, 1965) that in semiconductors in which the intervalley scattering does not play an important role in the electron-lattice energy balance, the piezoresistance should have a nonmonotonic dependence on the field. To this end the authors investigated samples of n-type germanium, cut along the <111> direction from a single crystal ingot with electron density $3.25 \times 10^{13} \text{ cm}^{-3}$ and mobility $2.6 \times 10^4 \text{ cm}^2/\text{v-sec}$, at 77K. The electric field was applied along the crystal and its deformation was effected in the same direction. The field was applied

in the form of rectangular pulses of 0.2 μ sec duration and repetition frequency 10 -- 15 cps. The dependence of the resistance on the pressure was linear up to 300 kg/cm² and the experiments were carried out in the linearity region. The results (Fig. 1) confirm the theoretically deduced nonmonotonicity of the piezoresistance. This confirmation, however, is only qualitative, and quantitatively the minimum of theoretical curve, and the experimental change in the piezoresistance due to the

TITLE: Dependence of the anisotropy of scattering of current carriers in n-Ge on the impurity concentration

SOURCE: Fizika tverdogo tela, v. 8, no. 8, 1966, 2511-2513

TOPIC TAGS: semiconductor carrier, germanium single crystal, carrier scattering

ABSTRACT: The anisotropy parameter $K = \mu_{\perp} / \mu_{\parallel}$ was measured at the liquid nitrogen temperature on single crystals of n-germanium doped with antimony. The carrier concentrations were between 3×10^{13} and $8 \times 10^{17} \text{ cm}^{-3}$. Fig. 1 shows the measured anisotropy of mobility versus the carrier concentration in n-Ge. Curve 1 represents results obtained without considering interelectronic interaction, and curve 2 shows them with this interaction taken into account. With the exception of very high concentrations ($n \approx 5 \times 10^{17} \text{ cm}^{-3}$), a good agreement was obtained between the experimental results and the curve calculated by allowing for the electron-electron interaction. The value of $\tau_{\parallel}^{(a)} / \tau_{\perp}^{(a)}$, which characterizes the anisotropy of the relaxation time for acoustic scattering, was found to be 1.52. Authors thank V. N. Vasilevskiy and A. N. Kvasnitskaya for supplying certain germanium samples and V. M. Vsetskiy for his assist-

pp 197-200

ABSTRACT: Preliminary communications are presented on experiments in electrolysis with separation of the cathode and anode spaces by a partition with a hole. In some cases the partition used was a dielectric and in others it was a metal. It was found that when the electrodes are at a short distance from a partition with a round hole (5-15 mm), the deposit on the cathode has a central spot around which there is a number of concentric circles; if the aperture is in the form of a slit, there is an oval spot and a series of concentric ovals. The phenomenon described was observed independent of the metal (Me) precipitated and the composition of the electrolyte. The anode also revealed uneven dissolution of the Me, with formation of rings or ovals.

TITLE: The Phenomenon of Zone Formation on Electrodes in the Process of the Electric Crystallization of Metals (Tavleniye zono-obrazovaniya na elektrodakh v protsesse elektrkristallizatsii metallov)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 120, Nr 3, pp.552-553 (USSR)

ABSTRACT: The authors investigated the electric precipitation of alloys (Cu-Pb, Cu-Zn, Cu-Bi, Cd-Bi, Cu-Sn) as well as of pure metals (Cu, Ni, Co, Zn, Bi and others) and of the dissolution of copper on the anode under conditions analogous to those prevailing during the experiments carried out by Arndt (Ref 4). In all cases distinctly marked concentrical zones were formed. According to radiographical tests the precipitations of the alloys in the various zones differ by their phase composition. The nonuniform current distribution on the cathode gives rise to different values of the potential in the center and on the periphery of the cathode. The authors carried out measurements of the potential of the cathode in its various parts. A diagram shows the curves obtained for

Card 1/3

SOV/20-120-3-32/67

The Phenomenon of Zone Formation on Electrodes in the Process of the Electric Crystallization of Metals

the change of potential with increasing distance from the center of the cathode. The material found experimentally seems to indicate that transition from one zone to another takes place at certain strictly definable potentials only. The character of zone distribution depends on the composition of the electrolyte as well as on the distribution of the current on the surface of the electrode. Also in the course of the electric precipitation of pure metals the forming of zones may be observed. In this case the zones are distinguished from one another by the size, orientation, and by the nature of the boundaries of the crystals contained in them. In the case of the deposits of pure metals the forming of zones is apparently due to the difference in the electrochemical conditions of the precipitation. There are 2 figures, 1 table, and 8 references, 3 of which are Soviet.

TITLE: The Dependence of the Structure of the Surface of Electrolytic Deposits of Alloys on Their Phase Composition (Zavisimost' stroyeniya poverkhnosti elektroliticheskikh osadkov splavov ot ikh fazovogo sostava)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol 123, Nr 4, pp 720-721 (USSP)

ABSTRACT: Extensive material has hitherto been collected concerning electric deposits of alloys. However, the influence exercised by structural factors and the character of component interaction in the formation of alloys (by which the physico-chemical properties of the coating are, to a great extent, determined), have received but little attention. According to the results obtained by the present paper the forming of the non-equilibrium phase of an oversaturated solid solution is connected with a considerable structural variation of the surface of the deposit. In order to reduce the influence exercised by secondary factors upon the surface structure of deposits to a minimum, investigations were carried out on such metals as permit common depositing without the addition

Card 1/4

SOV/20-123-4-41/53

The Dependence of the Structure of the Surface of Electrolytic Deposits of Alloys on Their Phase Composition

of surface-active or complex-forming substances to the solution. The system copper-bismuth is particularly well suited for this purpose. When using the solution $\text{Cu}(\text{ClO}_4)_2$ 0.6 N, $\text{Bi}(\text{ClO}_4)_3$ 0.4 N, pH 0.6 (solution I), alloys were obtained which contain the phase of the oversaturated solid solution of bismuth and copper (with a corresponding increase of the copper lattice parameter up to $3.635 - 3.645 \text{ \AA}$). The bismuth content in the solid solution increased with current density and, according to the data of radiographic measurements, it attained 12 per cent by weight. With a further increase of current density, the lattice was disturbed to such an extent by the increase of oversaturation, that the lines on the X-ray picture vanished completely. A figure shows electron-microscopic pictures of deposits of alloys with different bismuth content. With an increasing oversaturation of the solid solution, the surface of the deposit becomes smoother, and if oversaturation is considerable it becomes glossy. The deposits forming in a solution $\text{Cu}(\text{ClO}_4)_2$ 0.2 N, $\text{Bi}(\text{ClO}_4)_3$ 0.8 N, pH 0.6 (solution II) are a mixture of pure copper-

Card 2/4

SOV/20-123-4-41/53

The Dependence of the Structure of the Surface of Electrolytic Deposits of Alloys on Their Phase Composition

and bismuth crystals. The dependence of deposit structure of an alloy on its phase composition is confirmed also by the data on copper-tin and tin-lead alloys. The third figure shows a photograph of the surface of the deposit of the alloy copper-tin. This deposit was of a dense and finely-crystalline nature. When obtaining a tin-lead alloy from the solution $\text{Sn}(\text{ClO}_4)_2$ 0.8 N, $\text{Pb}(\text{ClO}_4)_2$ 0.2 N, HClO_4 1N, no forming of oversaturated solutions was observed according to the data obtained by radiographic investigations. Deposits had a coarse-crystalline structure. The forming of oversaturated solid solutions exercises an essential influence upon the structure of electrolytically deposited alloys in that it promotes the formation of finely-crystalline deposits. Finely-crystalline and glossy deposits are thus to be expected whenever electrochemical conditions promote the production of oversaturated solid solutions. There are 3 figures and 11 references, 6 of which are Soviet.

TITLE: Electrodeposition of magnetically-hard alloys, Part I. Electrodeposition of a cobalt-phosphorus alloy

SOURCE: AN SSSR. Institut nauchnoy informatsii. Informatsionnyye sistemy (Information systems). Moscow, 1964, 117-121

TOPIC TAGS: magnetic memory, magnetically hard alloy, alloy magnetic property, alloy electrodeposition, cobalt alloy, phosphorus containing alloy

ABSTRACT: The authors call attention to the interest centering on the development of miniaturized machine memories using thin magnetic films for high-density information storage and to the use of electrodeposited ferromagnetic alloys for these purposes. The magnetic coverings used in information storage must possess a high coercive force (better than 500 oersteds), residual induction and orthogonality factor; that is $B_r/B_m > 0.5$. The work reported on in this article was carried out in the Laboratoriya elektromodelirovaniya (Electrosimulation laboratory) of VINITI for the purpose of determining and investigating the properties of magnetically-hard alloys employed in the recording stage of the overall information-storage problem. Of the different alloys presently in use as carriers of
Card 1/3

L 32905-65

ACCESSION NR: AT5004145

recorded informations, the authors focused their attention in particular on the study of the magnetic characteristics of Co-P alloys, since, according to the structural diagram, at specific compositions one can expect the electrodeposition of heterogeneous alloys possessing a high coercive force. The purpose of the present work was to investigate the effect of the conditions of the deposition and the composition of the electrolyte on the composition, quality, structure, magnetic properties and current efficiency of the Co-P alloy. The tests were conducted in glass electrolyzers of 0.5-1 liter capacity, with a thermostat used in high-temperature work. The pH of the electrolyte was checked by a glass electrode and an LP-58 potentiometer. The magnetic properties were determined through the use of a device not described in this article, while current efficiency values were verified by means of a copper coulomb-meter. Polarization measurements were made in a special thermostatically-controlled cell, and the electrodes were subjected to preliminary purification by activated carbon and low-density current. Other test procedures and a concise description of the methodology employed in the preliminary investigations are outlined in the article. The buffer properties of the electrolyte are discussed in a separate section. The results, presented primarily in graph form, indicate the following basic conclusions: 1. the coercive force of pure electrolytic cobalt increases somewhat as the cobalt concentration in the solution increases and then shows no further change; 2. the pH

Card 2/3

L 32905-65

ACCESSION NR: AT5004155

of the solution has the most marked effect on the magnetic properties of the depositions, with an increase in pH above 3-4 resulting in low precipitate quality; 3. the temperature of the solution also has a considerable influence on the magnetic properties of the depositions, with maximum coercive force achieved at temperatures of 25-40 C; 4. as the current density is increased, the coercive force passes through a maximum, shifting toward lower densities as the temperature is lowered; optimal current densities are: 2.5 amp/dm² for 20 C and 5-10 amp/dm² for 40 C; 5. for the electrodeposition of a Co-P alloy possessing a coercive force of 600-800 oersteds and an orthogonality factor of 0.55-0.6, an electrolyte of the following composition is recommended: CoCl₂ · 6H₂O 200-400 g/liter; NH₄H₂PO₂ 25-100 g/liter; Trilon B 10-15 g/liter, pH 1.8-2; temperature 20-40 C, current density 2.5-5 amp/dm². TITLE: Electrodeposition of magnetically-hard alloys. Part II. Electrodeposition
of cobalt-nickel-phosphorus and cobalt-manganese-phosphorus alloys

BT1

SOURCE: AN SSSR. Institut nauchnoy informatsii. Informatsionnyye sistemy (In-
formation systems). Moscow, 1964, 124-127

TOPIC TAGS: magnetic memory, magnetically hard alloy, alloy electrodeposition,
cobalt alloy, nickel alloy, phosphorus containing alloy, manganese alloy, alloy
magnetic property

ABSTRACT: For the purpose of expanding the assortment of alloys which may be
used in information recording (computer storage applications), and also of de-
veloping electrolytes to operate in a wider pH interval, the authors studied the
effect of nickel and manganese ions on the electrodeposition of a Co - P alloy. A
number of bibliographical references (most of them American) are cited in a dis-
cussion of the magnetic properties of Co - Ni alloys obtained by the electrodepo-
sition method. The authors call attention to the fact that Co-Ni-P alloys, chemi-
cally obtained, possess a coercive force of 4-14 oersteds and contain about 5% P

Card 1/3

L 32904-65

ACCESSION NR: AT5004146

and different quantities of nickel and cobalt (these alloys have been used in the manufacture of memory elements in high-speed computers). An investigation was made of the conditions for the electrodeposition of Co-Ni-P and Co-Mn-P alloys, and the effect of different factors on the magnetic properties and composition of the alloys was studied. For the electrodeposition of a Co-Ni-P alloy having a coercive force of 1000-14000 oersteds and a rectangularity factor of 0.7, an electrolyte of the following composition is recommended:

 $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ 100-200 g/l; $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$ 140 g/l; $\text{NH}_4\text{H}_2\text{PO}_2$ or NaH_2PO_2 25-100 g/l.

The pH of the electrolyte is 2.5-3, the temperature is 40C. For the electrodeposition of a Co-Mn-P alloy having a coercive force of 500-900 oersteds, residual inductance of 6000-9000 gauss and rectangularity factor of 0.65-0.85, the following electrolyte is recommended:

 $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ or $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$ 200-400 g/l; $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$ or $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$ 20-30 g/l;

Card 2/3

L 32904-65

ACCESSION NR: AT5004146

$\text{NH}_4\text{H}_2\text{PO}_2$ or NaH_2PO_2 25-50 g/l.

As a buffer admixture 10 g/l Trilon B may be added to the electrolyte, the deposition of the alloy occurring at a temperature of 18-40 C, pH 1.8-5. The current efficiency of the alloy is about 100% (cobalt anodes). Orig. art. has: 3 figures.

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 6, 1965, 101

TOPIC TAGS: electrolysis, magnetic alloy, cobalt, phosphorus, manganese, ammonium compound, sodium compound / Trilon B 2 }

ABSTRACT: This Author Certificate presents a method for electrolytic deposition of a magnetic ternary alloy containing cobalt and phosphorus. To obtain films of alloy cobalt-manganese-phosphorus, the process is conducted at a temperature of 18-40C, with current density of 1-10 amp/dm², and a pH of 1.8-5. The electrolyte contains sulfuric acid or chlorine salts of cobalt (200-300 g/liter), of manganese (20-40 g/liter), ammonium hypophosphate or sodium hypophosphate (35-50 g/liter), and Trilon B (10 g/liter).

TITLE: Anodic behavior of aluminum under electropolishing conditions

SOURCE: Ukrainskiy khimicheskiy zhurnal, v. 31, no. 4, 1985, 339-363

TOPIC TAGS: aluminum anode, electropolishing, anode potential, polarization curve, aluminum oxide layer

ABSTRACT: The article is devoted to a study of the anodic behavior of aluminum in $H_2SO_4 - H_3PO_4$ and $H_2SO_4 - H_3PO_4 - CrO_3$ aqueous electrolytes, aimed at determining the stable and unstable stationary portions of the polarization curve and also portions where the process of electropolishing takes place. $I - V$, $\Phi - t$, and $V - t$ curves were plotted. All the $I - \Phi$ curves display three distinct portions (see Fig. 1 of the Enclosure): in the first (a - b), the current density increases with the anode potential; the second (b - c) corresponds to the unstable anode potential, where a sharp rise in anode potential is associated with a smooth rise in current density; the third which has a negative slope, is associated with oscillatory processes (pronounced fluctuation of the anode potential and current intensity in the cell). It was found that the electropolishing of aluminum could be carried out best in the region of the portion having a negative slope: at the start of this

Card 1/3

L 53917-65

ACCESSION NR: AP5011420

portion, oxide layers are formed and broken down, marking the beginning of the electro-
polishing process. As the current density is increased further, the voltage becomes more
stable, and a high-quality electropolishing takes place. Orig. art has: 4 figures and 1
table.

TITLE: Electrodeposition of hard magnetic Co-Mn-P alloys

SOURCE: Zashita metallov, v. 1, no. 5, 1965, 534-538

TOPIC TAGS: cobalt alloy, manganese containing alloy, phosphorus containing alloy, magnetic alloy, alloy electrolytic deposition, electrolyte composition, alloy film magnetic property

ABSTRACT: Experiments have been made to determine the optimum conditions for electrodeposition of thin films of Co-Mn-P alloy with high magnetic properties. Copper rods or foil, or phosphorous bronze foil with an area of 4 cm², were used as cathodes, cobalt or platinum were used as anodes, and the electrolyte temperature was varied from 20, 40, and 60C, electrolyte acidity (pH) from 1.1 to 4.8, and current density from 0.5 to 5 a/dm². The best electrolytically deposited Co-Mn-P films — about 10-μ thick, with a saturation induction B_m of (8—11) x 10³ gs, a residual induction B_r of (6—7) x 10³ gs, a coercive force H_c of 800—6000C and a hysteresis-loop rectangularity factor B_r/B_m ranging from 0.65 to 0.85 — were obtained with an electrolyte containing 200 g/l CoCl₂·6H₂O, 25 g/l MnCl₂·4H₂O,

25 g/l $\text{NH}_4\text{H}_2\text{PO}_4 \cdot \text{H}_2\text{O}$, and 10 g/l Trilon "B"; the electrolysis conditions were: pH 1.8-4.8, temperature 15-50C, and cathode current density 2.5-1.5 a/dm². A unique feature of the electrolyte is the wide pH range in which deposits with high magnetic and decorative properties are obtained. Orig. art. has: 4 figures and 3 tables. [MS]

TITLE: Some problems of the alloy electrodeposition theory. VIII.
Study of the dependence of copper alloy phase structure on
the electrochemical conditions of deposition

PERIODICAL: Zhurnal fizicheskoy khimii, v. 36, no. 9, 1962, 1870 - 1876

TEXT: The electrodeposition of supersaturated solid solutions of lead, thallium, tin, or cadmium in copper from solutions of perchlorates (Pb-Cu, Sn-Cu, Cd-Cu) or of sulfates (Sn-Cu), or nitrates (Tl - Cu) was investigated. In all cases, the deposition of Pb, Tl, Sn, and Cd started at more positive potentials than would correspond to the equilibrium potential of these metals, and the lattice constant of the copper was greatly expanded. The solid Sn-Cu solution contained more than 22% Sn, the lattice constant was 3.75 Å, and at a cathode potential more positive than -130 mv the $Cu_{31}Sn_8$ phase (high-temperature δ -phase) was formed. The solid Cd-Cu

Card 1/2

Some problems of the alloy ...

5/076/62/036/009/001/011
B101/B102

solution contained ~16% Cd, the maximum lattice constant was 3.716 Å at -0.350 v. The supersaturation observed is explained as follows: Owing to high overvoltage, a highly active Cu lattice is formed in which the electro-negative metals have higher solubility, so that the separation potential becomes more positive. The lattice then loses its excess energy, and a supersaturated solid solution is formed. The supersaturation depends on the cathode overvoltage attaining 150 - 200 mv with H₂, and on the rate of electrodeposition. There are 4 figures.
