Title : of Ferrites.

Orig Pub : Izmerit. tekhnika, 1957, No 2, 46-49

Abstract : Description of a series-resonance bridge circuit for the determination of the magnetic parameters of ferrites in the frequency range from 20 kc to 12 Mc. The specimens were in the forms of toroids, on which a winding was placed. The circuit can be used to measure ferrite coils with inductances from tens of millihenries to tens of microhenries and impedances from 5 to 1000 ohms with errors of 1 and 5% respectively.

Methods of Determining the Properties of Electrotechnical Steel
(K voprosu o metodike opredeleniya svoystv elektrotehnicheskoy
stali)

PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 4, pp 437-439 (USSR)

ABSTRACT:

Because of the new electrotechnical steel types worked out recently which can be used at higher frequencies, the magnetic characteristics of the GOST for the audio-frequencies of 400, 500, 1000, 2400, 4800 and 8000 cycles must be extended. The following magnetic characteristics are recommended: 1) The basic curve of magnetization under dynamic conditions, 2) The function of all the specific losses of the maximum magnetic induction, at corresponding frequencies of the magnetizing current, 3) The limiting hysteresis loops at different frequencies, and the corresponding parameters, 4) The material characteristics under conditions of a combined magnetization by 2 different fields. Tests in weak magnetic fields and at higher frequencies are best carried out with definitely dimensioned ring-shaped samples. According to GOST 802-58, tests of sheet metals must be carried

Card 1/3

SOV/32-25-4-23/71

Methods of Determining the Properties of Electrotechnical Steel

out in weak magnetic fields with band samples which are overlapped on both sides to secure a better magnetic contact. Besides indications on tests with Epstein's device, the following devices are recommended: voltmeter of the type MVI-1 M, wattmeter of the type D-522 (for 50 cycles), and of the type D-542 (for higher frequencies) which are manufactured by the "Toch-elektronika" Works. The VNIIM designed a diode voltmeter VL and a thermoelectric wattmeter VMT-2 (measuring range 10-200 v and 0.1-10 a ($\cos \phi = 0.2$)) which are combined with auxiliary devices and a measuring device to constitute the special unit of the type UMIPT-1. The latter is used for tests of magnetic-soft materials under dynamic conditions, in the frequency range of 50-8000 cycles. Measurements of magnetic properties according to the primary harmonic waves of the field tension and induction can be made at the bridge plant of type K 520 ("Toch-elektronika" Works) at 500, 1000, 2400 and 4800 cycles. The same factory designed the devices U-55 and U-542 for the frequencies of 50 cycles. Even after a waiting time of 10 minutes subsequent to demagnetization as suggested by GOST 802-58, great variations of the magnetic state can be observed.

NOTICE: This book is intended for technical personnel working in the field of electric power systems and in electrical measurement laboratories or plants.

CONTENTS: This is a collection of reports presented at a conference on the overall development of the Soviet electrical industry held in Kiev on October 22-27, 1956. The conference was convened by the Institute of Electrical Materials at USSR (Institute of Electrical Engineering, Academy of Sciences) and the members of responsible organizations and enterprises of the heavy engineering industry. Problems relating to electrical instrumentation as a whole (reports by A. D. Baranovskiy, P. F. Orenstein, Yu. M. Avetisyan, Ye. G. Shulman) were discussed, as well as problems relating to the development of reference instruments (Yu. M. Avetisyan, T. M. Shulman), the automation of electric-measuring circuits (Yu. M. Baranovskiy, Yu. M. Klyushnikov) and to the economy of the Republic. No personalities are mentioned. References are given at the end of the reports.

CONTENTS: I. Apparatus for Measuring the Magnetic Character-

istics of Materials. II. Apparatus for Measuring the Magnetic Character-

istics of Materials and Used for Measuring Magnetic Fields

entirely or partly materials and used for measuring magnetic fields

characteristics.

TITLE: Accurate measurements of magnetic parameters in science
and technology

SOURCE: Izmeritel'naya tekhnika, no. 4, 1964, 46-49

TOPIC TAGS: magnetism, magnetism measurement, nuclear resonance,
paramagnetic resonance

ABSTRACT: The following magnetometric standards are presently used
in the USSR; the unit of magnetic field intensity is established
by means of a quartz Helmholtz coil 312 mm in diameter and having
an accuracy of 0.001%. Magnetic flux is established with a Campbell
coil of 300 mm and 480 mm diameter, for the primary and secondary
coils, respectively, with an error of 0.004%. These values are then
transferred to industrial measuring instruments with an accuracy
varying from 0.01 to 0.1%. Recently, the phenomenon of magnetic
nuclear resonance has come into use as a standard for measuring the

Card 1/3

ACCESSION NR: AP4038454

intensity of magnetic fields from tens to millions of amps per m with an accuracy of a few thousandths of one percent. Other phenomena such as paramagnetic resonance and optical pumping have also been used for highly accurate measurements of very weak magnetic fields. Current scientific developments call for instruments capable of measuring the geomagnetic field and also extraterrestrial magnetic fields with an accuracy of 1×10^{-3} amp/m, that is, about 0.002%. In 1964 at the National Economy Fair, instruments were displayed for the determination of atomic constants (gyromagnetic ratio) designed by VNIIM (All-Union Scientific Research Institute for Netronomy) and KhGIMIP (Kharkov State Institute of Measures and Measuring Instruments). One device measures weak magnetic fields within an accuracy of 0.002%; another instrument, the IMP-3, is used to measure the gyromagnetic ratio from 40 to 1200 kiloamp/meter. An instrument similar to the IMP-3, with a range of 1—10 kamp/m and accurate to within 0.05%, was also shown. Some of the new developments scheduled for the next 10—15 yr to satisfy the demands of Soviet economy include a change-over to magnetic standards based on elementary particle constants with an accuracy of 0.0005%, the general use of the nuclear resonance method and optical pumping

TITLE: A method for producing polyvinylchloride. Class 39, No. 170671

SOURCE: Byulleten' izobrashcheniy i tovarnykh znakov, no. 9, 1965, 70

TOPIC TAGS: polyvinylchloride, suspension polymerization, hydrolysis

ABSTRACT: This Author's Certificate introduces a method for producing polyvinylchloride by suspension polymerization of vinyl chloride in the presence of a dinitrile of azoisobutyric acid as initiator and in the presence of a stabilizer.¹⁵ Products of caustic hydrolysis of polyacrylonitrile are used as the stabilizer to improve the quality of the polyvinylchloride.

TITLE: Simple Methods of Spectral Analysis of Inert Gases for Impurities
(Uproshchennyye metody spektral'nogo analiza inertnykh gazov na primesi)

PERIODICAL: Optika i spektroskopiya, 1959, Vol 6, Nr 6, pp 818-820 (USSR)

ABSTRACT: The authors described earlier (Ref 3) a simple method of spectroscopic determination of the nitrogen content of argon, suitable for use under industrial conditions. The spectral instrument was replaced by a filter which separated out the required part of the spectrum. The discharge was excited in a capillary by a high-frequency oscillator and argon was drawn continuously through the capillary by means of a mechanical pump. Emission proportional to the amount of nitrogen was recorded by means of a photomultiplier FEU-19 connected to a microammeter. The sensitivity of the method was 0.01% and its precision ~10%. This simple method of analysis was applied also to determination of the amount of hydrogen in helium, neon in helium and neon-helium mixture in nitrogen. A table on p 820 gives the range of impurity concentrations which could be measured, the filters and the receivers used as well as the diameters of the capillary and pressures in it. Since only small amounts of the gases were available the discharge tubes used in the investigation reported here had capillaries closed at one end; such a capillary is denoted by

SOV/51-6-6-25/34

Simple Methods of Spectral Analysis of Impurities in Inert Gases

3 in Fig 2 (1 and 2 are electrodes). The discharge was excited by one of the following: (1) an oscillator VG-2, (2) a low-power oscillator based on the GU-29 tube and whose working frequency was 30 Mc/s, (3) a pulse magnetron which produced 3 cm waves. The reproducibility of the results was 5-6% when (2) or (3) were used but it fell to ~10-15% when the oscillator VG-2 was employed. To construct calibration curves (microammeter current v. concentration, Fig 1) the authors used standards in the form of mixtures of known compositions. There are 2 figures, 1 table and 3 Soviet references.

"Thermobaric Field of the Troposphere Over Moving Anticyclones"
Trudy In-ta matem. i mekhaniki AN UzSSR, No 12, 71-75, 1953

The authors study the motion of 30 anticyclones in comparison with the form of the baric field at the level of the mean troposphere and with the peculiarities of the temperature field of the lower half of the troposphere. They work out three prognostic schemes: isohypes of absolute topography, isohypes of relative topography, center of anticyclone near the ground at the initial moment. (RZhGeol, No 6, 1954)

TEXT: The purpose of the work is the study of the property of thermobaric fields with rapid increase or decrease of pressure near the earth. As a criterion of the process intensity, the change in pressure near the earth for 3 hours by the magnitude of 5 mb or more was chosen. The magnitudes of the first, second, and third derivatives in the vicinities of the point of maximum change in pressure were studied. Finite differences were used in the calculations of the derivatives. Hereat, the problem arises naturally, in what a manner the choice of the step of the independent variable affects the magnitude of the finite difference, and what is to be adopted as the true magnitude of the derivative. Here the following assumption can guide: as magnitude of the derivative, the first value of the

Card 1/3

finite difference must be taken, starting from which it does not vary (within the limits of errors), if the step of the independent variable decreases in succession. The values 1,000, 750, 500, and 250 km were chosen, the axes of rectangular coordinates were chosen in the following manner: One axis was directed along the tangent to the isohypse, and the other one along the normal to the latter toward increasing geopotentials. In general, with regard to the first differences of the geopotential, one can say that the centers of the isallobaric regions have no specific properties in comparison with other points of the frontal zones. The horizontal gradient of the geopotential increases with the altitude and has the greatest value at the 300 mb level. The computed values of the second and third derivatives represent a considerably more complicated pattern, which is evident from the tables presented in the work. Their analysis leads to the conclusion that the derivatives, computed for the 1,000-km step, smooth out highly the properties of the thermobaric fields of the atmosphere. This pertains mostly to the third differences in so far as the computation in this case is carried out over the field above the area $3,000 \times 3,000 \text{ km}^2$. Over such a wide area, the structure specific features of the thermobaric fields above any region are leveled

Card 2/3

A005/A001

The Thermobaric Fields of Regions With Large Variations of Pressure

down completely. Therefore, the step of 1,000 km cannot be recommended for the characteristic of the structure of high-altitude frontal zones. On the other hand, the step of 250 km is too small and unsuitable because it is not possible at the present state of the aerological techniques to ensure the required accuracy. Moreover, with this step the change of the curvature cannot be calculated at all. Therefore it is recommended to choose the step within the limits 500-750 km. The advection of the geostrophic eddy was also calculated. It turned out that it is of the same order of magnitude as the advection of the deviation of the eddy from the geostrophic one. Therefore, in estimating the change of the geopotential in time, one can confine oneself to take into account the transfer of the geostrophic eddy in the case when only the sign of this change is being determined. But if one encounters the problem of calculating the changes of the geopotential, it is necessary to take into account both the transfer of the geostrophic eddy and the transfer of the deviation of the eddy from the geostrophic one.

TITLE:

Characteristics of Air Flows Over the Pamir and West
Tyan'-Shan'

PERIODICAL:

Meteorologiya i gidrologiya, 1959, Nr 9, pp 3 - 12 (USSR)

ABSTRACT:

Some conclusions on the circulation of the atmosphere in summer and autumn according to the data of the expeditions in 1956 and 1957 are put forward here. These expeditions were carried out by the following authorities: Institut matematiki i mehaniki AN UzSSR (Institute of Mathematics and Mechanics of the AS Uzbekskaya SSR), Sredneaziatskiy nauchno-issledovatel'skiy gidrometeorologicheskiy institut (Soviet Central Asia Scientific Research Institute of Hydrometeorology), and Sredneaziatskiy gosudarstvennyy universitet (Soviet Central Asia State University). These expeditions had the task to investigate the structure of the jet current and the course of synoptic processes over the mountain district. The expedition of 1956 lasted from July 27 to August 22. Radio soundings were carried out once in 24 hours at the following places: Dzhambul,

Card 1/3

Characteristics of Air Flows Over the Pamir and
West Tyan'-Shan'

SOV/50-59-9-1/16

Arkit, Osh, Lake Kara-Kul', Kzyl-Rabat. At the same places, and in Namangan and Sary-Tash, pilot balloon observations were made three times in 24 hours. In 1957, the work was carried out from September 1 to 27 in Dzhambul, Aflatun, Osh, Sary-Tash, Lake Kara-Kul'. Radio soundings were made in the morning and evening, pilot balloon observations were made 3 times in 24 hours. At the same time, the expedition of the Moskovskiy gosudarstvennyy universitet (Moscow State University) under the direction of B. S. Chuchkalov was in Tokhtamysh (about 100 km north of Kzyl-Rabat). This expedition made the aerological observations according to the same program.- A detailed aerosynoptic analysis of the whole period, during which the expedition was working, is a matter of the future. Only some mean characteristics of the jet current over the mountain district are put forward here. 4 vertical sections are shown. The first on figure 1 along the meridian of 64° eastern longitude over the plains, the second along the meridian of 73° eastern longitude across the mountain systems of Soviet Central Asia in figure 2. Figures 3 and 4 show sections along the same meri-

Card 2/3

Characteristics of Air Flows Over the Pamir and
West Tyan'-Shan'

SOV/50-59-9-1/16

dians for 1957. An analysis of these 4 sections is given here. The first two show that in summer the velocity of the west wind at the jet-current axis increases from the plain towards the mountains, attains its maximum over the massif of Soviet Central Asia, and then decreases. The very interesting characteristics of the tropopause over the mountain district will be dealt with in a particular paper. A comparison of the median sections over the plains and mountains in September 1957 (Figs 3 and 4) with those in summer (Figs 1 and 2) shows that the amount of displacement to the south is different over the plains and over the mountains. The cause of this may be found in the analysis of the mean temperature field. Figures 3 and 4 show that the real wind over the mountains is stronger than the geostrophic wind in front of them. The sections shown permit the conclusion that the influence exercised by the huge mountain systems of Soviet Central Asia on the formation of the wind field acts up to a height of at least 16 km, i.e. it exceeds the height of the mountains by 3-4 times. There are 4 figures, 1 table, and 13 references, 11 of which are Soviet.

TITLE: Some patterns of movement and development of isotach maxima in jet streams			
CITED SOURCE: Tr. In-ta matem. AN UkrSSR, vyp. 27, 1963, 18-25			
TOPIC TAGS: isotach, jet stream, steering current, wind			
TRANSLATION: The steering current concept is applied to the movement of regions of isotach maxima (regions of the strongest wind) at the jet stream level. The movement of isotach maxima and change in their intensity under different conditions of atmospheric circulation occurs differently. In summer, the maximum velocities of movement of the isotach maxima in zonal jet streams are 14-16° of latitude in 12 hours, but in the case of southwesterly jet streams they are approximately 12° of latitude. The maximum wind velocities can weaken or increase in 12 hours by 100 km/hour or more in zonal jet streams but by not more than 60 km/hour in southwesterly jet streams. The isotach maxima are moved along the steering current, which is created by the jet streams themselves in the planetary high-level frontal			
Cord 1/2			

L-3752-65

ACCESSION NR: AR5008605

zones; in this case the velocity of movement of the isotach maximum is far less than the velocity of the wind forming this maximum. All changes in direction and velocity of the steering current conform precisely to the movement of the isotach maximum and therefore the trajectories of both are curved greatly in many cases and can even have the form of almost closed circles or ellipses. The most characteristic regions of a high-level field, where the isotach maxima are originated (isotach maxima generators) are: a region of strong convergence of counter-flows meeting at an angle of 180° ; place of merging of an ultrapolar trough with a zonal flow (angle close to 130°); merging of a meridional high-level trough with a zonal flow (angle of merging approximately 90°); southern part of a meridional trough where a closed cyclonic center develops rapidly; extensive, usually ultrapolar troughs when there are planetary high-level frontal zones bordering two troughs, seemingly fitted into one another; region of merging of jet streams of extensive gently sloping troughs where flows meet at angles of $30-45^{\circ}$. Almost every one of these circulatory systems has a similar corresponding system but of opposite sign where the air flows diverge and the systems of isotach maxima weaken or are annihilated. The article is accompanied by diagrams of possible "generators" and "annihilators" of the regions of isotach maxima. The authors give the laws of change in intensity of regions of isotach maxima. Z. Makhover.

TITLE: Static characteristics of motion of isotach maxima in jet streams according to charts of maximum wind

SOURCE: Tashkent. Sredneaziatskiy nauchno-issledovatel'skiy gidrometeorologicheskiy institut. Trudy, no. 19(34), 1964. Voprosy regional'noy sinoptiki Sredney Azii (Problems in regional synoptics of Central Asia), 38-56

TOPIC TAGS: jet stream, weather forecasting, meteorology, climatology, wind, isotach

ABSTRACT: The motion of regions of closed isotachs, greater than or equal to 100 km/hr, on the maximum wind surface in jet streams is studied. Operational charts of maximum wind, compiled by the Central Institute of Forecasting for January and July 1960, were used as working material. A review of the working data is given, including a breakdown of jet streams by type (polar front, arctic front, subtropical), the month of observation, and subcategories of circulation type. A study is made of the duration of existence of the isotachs observed.

Card 1/4

results are tabulated and plotted as shown in Fig. 1 on the Enclosure, and a discussion of the causes of the observed frequencies is given. A second frequency study is made according to the intensity of isotach maximum as classified by basic jet stream types. The study is then further subdivided to indicate the frequencies corresponding to characteristic types of circulation observed for each of the three jet stream types. The data are also tabulated to indicate the frequency of occurrence of selected ranges of translational velocities, and correlation is made between the mean rate of motion of isotach maxima and the qualitative characteristics of variation of intensity. In the latter analysis the intensities are simply grouped according to weakening, increasing, or static intensities, with summary tables given for each basic jet stream type. In turn, the data for intensity variation are correlated with translation rates of isotach maxima for four basic types of circulation. The authors disclaim any over-generalization of conclusions stemming from the analysis presented due to the limited number of observations made. The suggestion is made to expand the study on the basis of further data. Orig. art. has: 16 tables and 1 figure.

ABSTRACT: The techniques, procedures, and calculations used to determine the concentrations of thorium and radon decay products present in the atmosphere over the Moscow area from 1959 through 1961 are described. Results of these determinations are compared with the amounts of seasonal and daily radon exhalation from the soil measured in the surface boundary layer of the atmosphere. An attempt is also made

Summary. This book is intended for scientists, engineers and technicians working in the synthetic rubber, plastics, and petroleum rubber industries, and in scientific research institutes affiliated with these industries.

Contents. This book contains articles which report on research carried out at the Gomel'sk Scientific Research Institute for Synthetic Rubber (Gomel'sk Scientific Research Institute for Synthetic Rubber and Plastics), the International Poly. Institute, and the Gomel'sk Research Institute for Synthetic Rubber.

(Photo Reprinted from Sov. Polym. and Techn. Institute of the Synthetic Rubber Industry) In the experiments of Kovalev, Stepanov, and others, consideration is given to the synthesis of aromatic, aliphatic, and cyclic hydrocarbons. The methods of synthesis of aromatic hydrocarbons are described. The methods of synthesis of aliphatic hydrocarbons are described. The methods of synthesis of cyclic hydrocarbons are described.

TITLE: Metallographic investigation of porosity in magnesium-reduced titanium sponge

SOURCE: Tsvetnyye metally, no. 10, 1965, 70-71

TOPIC TAGS: titanium, sponge metal, porous metal, porosity, metal grain structure, metal recrystallization

ABSTRACT: The structure of the titanium sponge produced by reduction with magnesium affects markedly the process of the vacuum separation of the sponge and particularly the degree of elimination of certain impurities. However, the available data on the porosity of Ti sponge are relatively limited, and besides the study of the structure of this sponge cannot be confined to porosity alone, since the internal structure of the sponge, i.e. its microcrystalline structure, also is of interest. Accordingly, the authors present the results of a metallographic in-
