Abstract: Description of epidemic of flu in the world since 1960 and in Moldavia in particular, in Winter and Spring of 1965 in several military units there; generally morbidity was about 15% and the disease was running a relatively mild course, presumably due to immune condition from the previous epidemic which was also caused by the influenza strain A₂. 1 Western, 5 Rumanian references. TITLE: Meteorological conditions and the shift of radioactive clouds formed as a result of nuclear explosions in the Sahara

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 8, 1962, 19, abstract 3B147. (Studii și cercetări științ. Acad. RPR Fil. Iași. Fiz. și stiente tehn., v. 12, no. 1, 1961, 35 - 44)

TEXT: Displacement of air masses and the meteorological conditions in the Mediterranean Basin after the nuclear explosions in the Sahara in 1960 are studied. After the first explosion (February 13) radioactive clouds were transferred to the central and eastern parts of Europe after they were caught by the fast eastern stratospheric streams which, in a fortnight, circulated the whole Globe. Radioactive clouds (derived from the second explosion of April 1) did not pass over the Rumanian People's Republic. The products of the third explosion (December 27) again penetrated into the eastern part of the Rumanian People's

"Modification of the Reticulo-Endothelial System in Burn Shock"

Bucharest, Revista Sanitara Militara, Vol 16, Special No., 1965, pp 183-187

Abstract: Studies in rats in burn shock injected with dye to determine the adequacy of the reticulo-endothelial system at various times following the burn. Early intensification of the system is followed by total exhaustion of function in 48 hours or so. Causes are discussed: central nervous system, endocrine system; overload by decomposed protein, plasma protein loss. This and other rat studies by authors indicated that the central nervous system and endocrine glands are the first to become exhausted, the reticulo-endothelial system follows.

I. Inst. d'Oncol., Bucarest - ACTA CHIR. BELG. 1958, 57/3 (242-250)

Illus. 4

A description is given of a highly original and very attractive method for preserv-

2645

ation of the duodenum, or, more accurately, of the duodenal transit, in cases of total or of very large subtotal gastrectomies. After resection of the lesion, the jejunum is divided and its proximal end is sutured to the oesophagus, with an end-to-end anastomosis. The distal end is sutured to the duodenum, also with an end-to-end anastomosis. As a result the food bolus passes through the duodenum in a direction the inverse of normal. This inversion appears to have no harmful effect on the transit. The procedure is extremely interesting, but has so far been carried out only three times, with one death.

TITLE: An aerodynamic chamber for inspecting the cylinders and heads of internal combustion engines by their aerodynamic resistance. Class 42, No. 179965

SOURCE: Izobreteniya, promyshlennyye obratstsy, tovarnyye znaki, no. 6, 1966, 90

TOPIC TAGS: aerodynamic test, aerodynamics, internal combustion engine, high pressure chamber

ABSTRACT: This Author Certificate presents an aerodynamic chamber for inspecting the cylinders and heads of internal combustion engines by their aerodynamic resistance. The chamber is connected to a measuring pipe which contains a throttle provided with a device for holding the inspected object and with a U-shaped liquid manometer. The latter records the pressure at the entrance to the measuring pipe, this pressure being indicative of the aerodynamic resistance offered by the inspected object. To provide a means for marking the object being inspected, the device contains a marking equipment with several scribes capable of producing a symbol corresponding to a given aerodynamic resistance. The liquid manometer of the pipe is provided along its

Card 1/2

ACC NR: AP6011246

height with photoresistors responding to the movement of the liquid level. The number of these photoresistors is equal to the number of scribes, and each resistor is electrically connected with one of the markers. To check the pressure in the chamber, a single photoresistor may be placed on the liquid manometer of the chamber and may be electrically connected to the marking device.

TITLE: Doubling of frequency of a finite-width spectral line in the case of wave interactions in a nonlinear medium

SOURCE: Radiotekhnika i elektronika, v. 11, no. 11, 1966, 1915-1926

TOPIC TAGS: nonlinear optics, frequency conversion, harmonic generation, second harmonic

ABSTRACT: The theory of generation of the second harmonic in a weakly nonlinear medium is generalized for the case of quasi-monochromatic signals. The correlation function and the spectrum of the second harmonic were calculated under the assumption that the fundamental frequency signal is a stationary narrow-band Gaussian process. Calculations were made for the cases when the dispersion of a medium within the line-width can be neglected and when it is significant. In the latter case new effects occur which are characteristic of processes of the nonlinear interaction of random-modulated waves. It was established that in the case when the group log times of the harmonic with respect to the fundamental are comparable to the correlation time of the fundamental radiation, the rate of growth of harmonics is retarded and the process of harmonic generation appears to resemble a noncoherent nonlinear scattering.

Title : Critical heat removal in the flow of non-boiling water,
for a circular space.

Orig Pub: Zh. tekhn. fiziki, 1956, 26 No 7, 1542-1555

Abstract: The results of the experimental determination of the magnitude of the critical heat flow q_* in cooling by non-boiling water are presented; q_* corresponds to the formation of a vapor film between the cooled solid surface and the flow of fluid. In the experiments, the magnitude of the critical heat flow was determined by the conditions at the point of critical heat removal, corresponding to the transition from active boiling in the boundary layer of film boiling. Two experimental set-ups were used, and these are schematically illustrated. Special emphasis is placed on the arrangement

Card 1/3

USSR/Fluid Mechanics. Heat Transfer

Abs Jour: Ref Zhur-Mekhanika, No 6, 1957, 6841

Abstract: of the working area, the design of equipment used to distinguish pressures, and the construction of the heat-emitting element. The methods of measurement and calculation of experimental quantities are described, and possible errors in their determination are evaluated. In the experiments, a regulated transformer was used to increase uniformly the voltage and current in the heat-emitting element. At the critical point of heat removal, the heat emitter usually burned out and an open circuit occurred: the desired quantities were measured at that time. The obtained experimental data are presented in the form of graphs and tables, the analysis of which yields empirical relationships determining the dependence of q_* on the velocity of the non-boiling water at the inlet to the working area (in the range of 1.5-15.1 m/sec), on the average value of the temperature of the water at the exit (from 14 to 137°), on the size of the clearance between the external tube and the cylindrical heat-emitting

Card 2/3

USSR/Fluid Mechanics. Heat Transfer

Abs Jour: Ref Zhur-Mekhanika, No 6, 1957, 6841

Abstract: element (varying from 0.5 to 5.6 mm), and on the pressure p (ranging from 1 to 22 atm. abs.). The effect of surface roughness on q_* is studied in detail. The relationship between the critical heat flow q_{*1} for a rough surface and q_{*0} for a technically smooth surface takes the form of $q_{*1} = \varphi q_{*0}$, where φ is an experimental coefficient, determined by the type of surface and the nature of the fluid. The values of φ presented refer to a pipe of 10 mm diameter for width $\zeta = 1.45 \pm 1.50$ mm, with a velocity of water (or mixture) equal to 2.77 ± 2.83 m/sec, and at a temperature of $40-45^\circ$. Seven titles in bibliography.

TOPIC: Magnetic fields passing an easy electric field

PUBLICATION: Zhurnal eksperimental'noi fiziki, No. 1, 1957, p. 107

TOPIC: Radio-frequency shield

ABSTRACT: Construction and design methods of shields against magnetic and electric fields are described. Such a shield is a more complex form of a metal sheet or strip around the magnet. An easy electric field passes easily through such a shield since the reluctance of iron is in the way of the magnetic flux. One of the shields (labeled "labyrinth") was intended for a betatron accelerator and had a 300 at 5 kc. As an exact calculation of electric-field distribution

TITLE: Stability of a partially compensated electron beam

SOURCE: Atomnaya energiya, v. 19, no. 3, 1965, 239-244

TOPIC TAGS: electron beam, electron plasma, particle beam, plasma instability, plasma stability

ABSTRACT: The conditions for stabilizing a partially compensated electron beam against bending were investigated. A beam of particles in a partially or totally compensated accelerator represents a peculiar plasma in which instabilities, linked with the interaction of a large number of charged particles, can appear. The most dangerous of the plasma instabilities is the one associated with beam bending. From previous investigations it was concluded that total stability can be achieved only in a strongly focused external magnetic field, and that Foucault current and weak focusing do not ensure stability. It was found that in a continuous spectrum of wave disturbance vectors, there is always a region of strong (with a relatively large increment) instability. In the case of a discrete spectrum (e.g., when an accelerator beam has a final length), the instability appears only when the beam

Card 1/2

L 01215-66

ACCESSION NR: AP5023762

current is larger than the critical one. Landau attenuation and radiative friction do not stabilize the instability. A weak dissipative instability caused by radiative friction was detected. In some cases, Landau attenuation stabilized this instability while in other cases it intensified it. Orig. art. has: 1 figure and 30 formulas.

TITLE: Magnetic mirror trap for prolonged confinement of electrons

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 2, 1965,
373-373

TOPIC TAGS: plasma electron oscillation, plasma containment, plasma injection,
magnetic mirror, magnetic trapping

ABSTRACT: The authors describe a magnetic-mirror trap (LN) with a simple system of external injection from an electron gun, designed to operate at $\sim 8 \times 10^{-10}$ mm Hg and for an electron containment time up to 40 seconds. The apparatus is intended for a detailed study of prolonged motion of individual electrons in the trap, and to investigate the behavior of a rarefied plasma. A diagram of the trap is shown in Fig. 1 of the Enclosure. The injector used was described by I. M. Samoilov (PTE no. 1, 24, 1959). The electrons were injected into the trap through one of the mirrors along the magnetic field and captured by rapid variation of the electric field produced by a special ring electrode. The degree of electron capture was determined from the current flowing in the collector circuit. The LN apparatus was used to measure the containment time of fast electrons up to 100 keV

energy. The maximum containment time attained was 40 sec at electron energy 20 kev in a vacuum 10^{-9} mm Hg. Under these conditions the number of electron oscillations in the trap reached 5×10^9 , and the number of Larmor revolutions reached 1011. "We are deeply grateful to G. A. Illinov for advice and V. G. Ponomarenko for continuous help in constructing and adjusting the equipment." Orig. art. has: 4 [02] figure(s). [02]

TITLE: Focusing of an intense electron beam in an accelerator tube 19

SOURCE: AN SSSR. Sibirskoye otdeleniye. Institut yadernoy fiziki. Doklady, 1965.
Fokusirovka intesivnogo elektronnogo puchka v uskoritel'noy trubke, 1-22

TOPIC TAGS: electron beam, linear accelerator, focusing accelerator, electron accelerator

ABSTRACT: The passage of an intense electron beam through a linear accelerator tube is being investigated. One of the basic related problems is the need for beam focusing, and although there exist numerous papers devoted to this question, none of them seem to discuss the dynamics of a relativistic beam taking into account its characteristic field and the presence of a longitudinal accelerating field. Consequently, the present authors develop the appropriate relativistic equations of motion, discuss an unaccelerated beam and an accelerated beam in a uniform field, present the theoretical foundations for beam focusing by means of a periodic field, and carry out the actual calculation of the periodic field within the accelerator tube. The authors give numerous diagrams which should be

TITLE: Stability of a partly neutralized electron beam

SOURCE: AN SSSR. Sibirs'koye otdeleniye Institut vadernoy fiziki, Doklady, 1954.
Ustoychivost' chasticino kompensirovannogo elektronnogo puchka, 1-23

TOPIC TAGS: electron beam, particle accelerator, plasma stability

ABSTRACT: The problem of stability of particle beams in accelerator is considered. One of the most troublesome features is the sinuous (bending) instability which is discussed by the author for a case of partly neutralized and exterior forces can originate the instability which always appears at a definite wave length band. There is always a region of strong (with a relatively large increment) instabilities in a continuous spectrum of perturbation wave numbers. In the case of line spectrum (for instance due to a finite beam length in accelerators) the instability takes place only for the beam current exceeding a certain critical value. Radiation and Landau's damping don't suppress the instability. A weak instability of a dissipation type was discovered as a result of radiation dampings. In some cases Landau's damping suppresses this instability, however, in other cases may intensify it. The investigation was carried out for the beam model having two threads (electron and ion) of fixed dimensions and uniform densities.

TITLE: Magnetic mirror designed for a lasting containment of electrons
SOURCE: AN SSSR. Sibirsckoye otdeleniye. Institut yadernoy fiziki. Doklady, 1957.
1-9 Lovushka s magnitnymi probkami, rasschitannaya na dilet'noye uderzhaniye elektronov,

TOPIC TAGS: 21, 44, 55 electron capture, electron gun, magnetic mirror machine

ABSTRACT: Design, arrangement and experiments with a magnetic mirror device are described. The device consisted of a vacuum chamber electron gun, solenoid, collector with grids and auxiliary equipment. It was designed for containment of electrons up to a period of 40 sec. An energy of about 100 kev was attained by electrons. Magnetic induction in the mirror was about 2.5 kilogauss with a mirror ratio of 2.5. Dimensions of the cylindrical vacuum chamber were $1600 \times 210\text{mm}$. The pressure was $3 \times 10^{-10} \text{ mm Hg}$. Under normal operational conditions the time of electron containment was about 15 sec. This time interval was increased up to 40 sec by doubling or tripling the magnetic field strength after the electron capture. In this case, the number of electron oscillations reached 5×10^9 and the number of Jarmor revolutions was 10^{11} . Significant decrease of the containment time has been observed for $P/R = 0.1$ where P is the radius of the electron orbit and R is the magnetic line curvature radius. This

L 9424-66

ACC NR: AT5022449

result demonstrates a non-adiabatic effect of electron motion in magnetic mirror geometry. A simple method of electron injection from external electron gun is described. The capture is the result of fast switching of the electric field of a special form. The authors express their deep gratitude to G.A. Blinov for his numerous advices given on obtaining a super high vacuum as well as to V.G. Ponomarenko for his continuous assistance at the erection and adjustment of the mirror machine. TITLE: Coherent instability of a beam in a chamber with non-conducting walls

SOURCE: Atomnaya energiya, v. 20, no. 4, 1966, 340

TOPIC TAGS: particle accelerator, particle scatter, magnetic field, test chamber,
kinetic equation, betatron beam, linear approximation

ABSTRACT: A study is made of the so-called coherent instability in an accelerator related to coherent scattering of particles in the magnetic field of the currents induced by the beam in the walls of the chamber. Instability arises due to the losses in the walls, which cause a shift in the phase of the induced currents with respect to the oscillation of the beam. The test chamber has two rather thick parallel walls made of laminated iron (magnet poles). The space between the walls is $2b$. The properties of such a wall are characterized by the effective constants

$$\mu = \frac{\delta + \mu_0 \Delta_0}{\delta + d} + i \frac{\mu_0 \Delta_0}{\delta + d}; \quad \epsilon = \frac{\delta + d}{\delta}. \quad (1)$$

Card 1/4

UDC: 621.384.60
1972 11-76

L 37729-66

ACC NR: AP6027660

Here $\Delta_0 = \sigma (2\pi\omega_0 - \mu_0)^{-1/2}$ is the thickness of the skin layer of the iron; μ_0 , σ are the permeability and conductance respectively of the iron; d is the thickness of the laminae; and δ is the distance between them.

Instability was investigated with the aid of a simplified kinetic equation; the field of the beam was determined by the reflected current method.

Neglecting Landau damping, the instability increment is equal to

$$\text{Im } \omega = 2\Omega_0 \frac{\psi}{\sqrt{1+\psi^2}} |\mu|^{1/4} \ln |\mu|^{1/4}; \quad (2)$$

$$\Omega_0 = \frac{e^2 N_1 \beta^2}{2m\gamma\omega_0 b^2}; \quad \psi = \frac{Im\mu}{Re\mu}.$$

where ω_0 is the frequency shift of betatron oscillations (ω_0) due to reflected currents; N_1 is the linear density of the beam; $v = \beta c$ is particle velocity; $\gamma = (1 - \beta^2)^{-1/2}$; the superscripts correspond to $|\mu| \ll 1$, the subscripts to $|\mu| \gg 1$. The thickness of the wall.

Card 2/4

I 37729-66
ACC NR: AP6027660

D > b; in the opposite case the following evaluation is valid:

$$Im\omega \sim \Omega_{n\gamma} \left(|\mu| \frac{D}{b} \right)^{\pm 1}. \quad (3)$$

The necessary condition for removing the instability with the aid of Landau damping has the form

$$\Delta(\omega - \omega_0) \geq \Omega_n \times \begin{cases} 1 - \left(\frac{\gamma a}{b} \right)^2, \mu > 1; \\ 1 - \left(\frac{a}{b} \right)^2, |\mu| \ll 1; \end{cases} \quad (4)$$

$$\Omega_n = \frac{\Delta N_1}{\gamma^2 m \omega_0 a^2}.$$

Here a is the beam radius; Δ is the scattering with respect to velocities (Δv) or due to nonlinearity ($\Delta \omega_0$); w , k are the frequency and wave vector of the Fourier component of beam perturbation; and Ω_n is the shift of frequency ω_0 due to the space charge of the beam.

Note that when $\mu \gtrsim 1$, stabilization becomes much easier for a given particle energy!

Card 3/4

L 37729-66

ACC NR: AP6027660

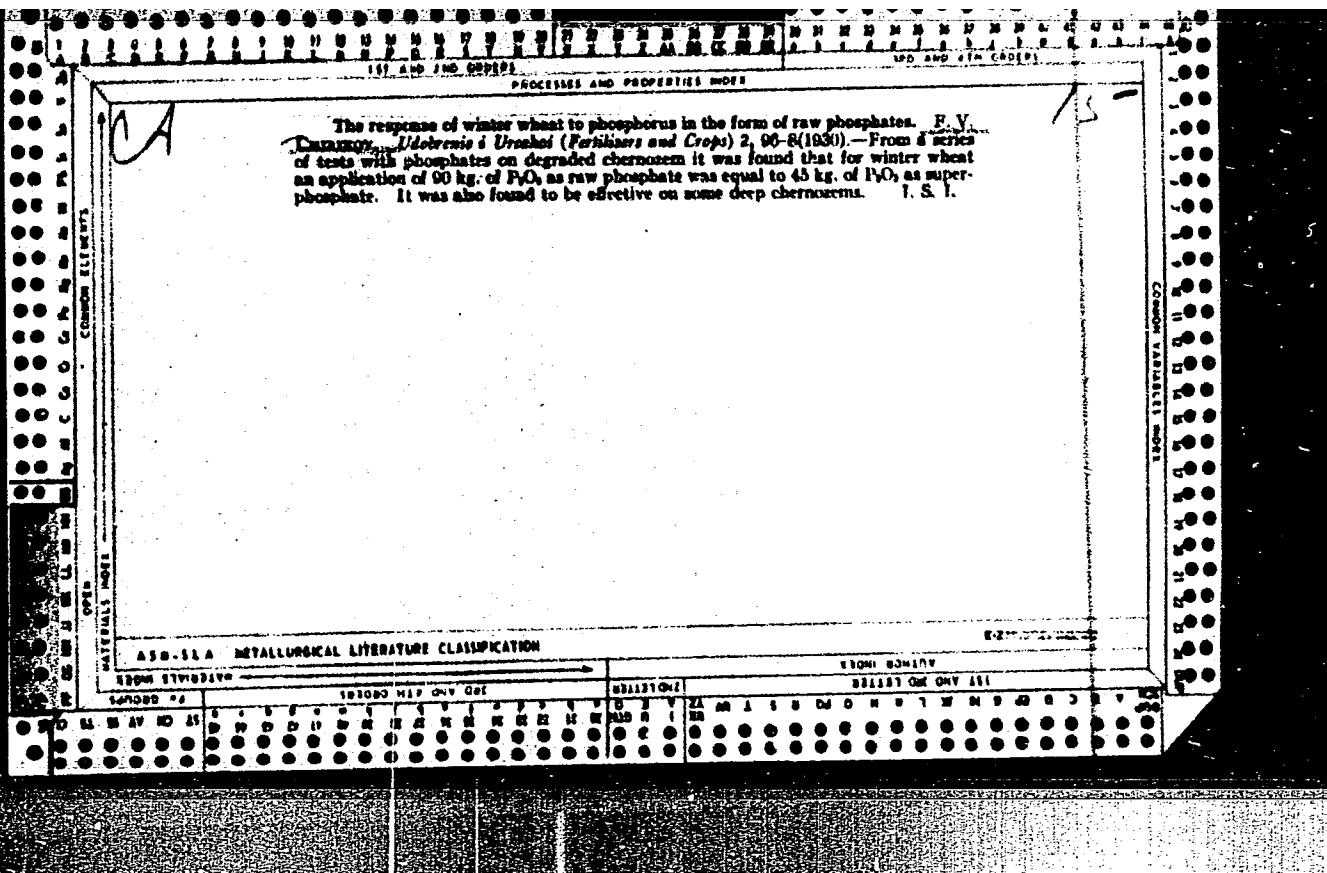

The following inequality, as a basic condition, must be satisfied
for the calculations to be applicable:

$$\frac{eb}{c} \sqrt{\mu s} \ll 1. \quad (5)$$

Instability arises only in the direction of the magnetic field.
All of the calculations were carried out by a linear approximation.

Availability of soil phosphates for the plant. P. V.
Chirkov. *J. rend. Acad. Sci. U. R. S. S.* 17, T. 10-42
(1937).—Percolation of a P-free nutrient soln. through
soil removed only small amounts of PO_4^{3-} from the soil, espe-
cially in neutral or slightly alk. types. The effect of plant
roots on the transference of reserve nutrients into sol-
lum is discussed. B. C. P. A.

Neutralized superphosphate. V. V. Chirkov and A. Ya. Strelcov. *Chimizdat Sotsialisticheskoy SSR* No. 6, 33-36 (1939); *Chimie & Industrie* 43, 317. On chernozem soil, superphosphate that has been neutralized with NH₃ up to 2% N or with 10-30% ground phosphite is equiv. to ordinary superphosphate; on the other hand, superphosphate that has been neutralized with NH₃ up to 8% N is less effective than ordinary superphosphate. On podzolic soil, a mixt. of superphosphate with 20% ground phosphite gives a higher flax straw and seed crop than normal superphosphate; increasing the proportion of phosphite decreases the complementary effect obtained. Generally speaking, neutralization of superphosphates with phosphite is preferable to other methods of neutralization on account of the increased P₂O₅ content obtained. A. Papineau-Couture

Assimilation by oats of phosphoric acid from various forms of phosphates. V. V. Chukay and E. P. Gusev. *Voprosy Uderenija, Tresoyuz. Nauch.-Issledovatel. Inst. Uderenij, Agrokh. i Agropochredeniya im. Gidroviza* 1959, No. 23, 3-32. Khim. Referat. Zhur. 1960, No. 2, 32; 1961, No. 1, 22. (22X). Results with oats were made on (1) soil from which mineral P_2O_5 had been washed out and org. P remained; (2) soil in which all P was transformed into the mineral form; (3) sandy soil to which no hanged soil has been added; (4) ordinary soil. The water-sol. P_2O_5 was extd. most nearly completely from ordinary chernozem and least from Kiviatized chernozem. $(NH_4)_2SO_4$ in soil cultures increased by 16-21% the utilization of P_2O_5 . In soil from which mineral P had been removed, $(NH_4)_2SO_4$ decreased the utilization of P, while in the same soils $Na_2SO_4 + CaCO_3$ increased the utilization of org. P by oats. On heated soils high yield of oats was obtained. The absorption of P_2O_5 by the plant in such cases was nearly equal to the absorption from normal min.

Plants and soil phosphates. E. V. Chirikov and A. A. Malyshev. *Pedology* (U.S.S.R.) 1947, No. 6, 200 XI (in English, 381 p.). Results with buckwheat, oats, pea, flax and mustard on deep chernozem, podzolized loam, and loamy fine sand show: (1) the capacity to give up P_2O_5 to the plants increases in the order: chernozem, podzolized loam, loamy fine sand; (2) a similar order prevails in these soils, with reference to H_2O -sol. P_2O_5 , after harvest of crops; (3) oats takes up most efficiently the H_2O -sol. P_2O_5 ; (4) the more P_2O_5 a 1:25 soil-water ext. shows, the more is taken up by plants; (5) plants do not exhaust all the H_2O -sol. P_2O_5 ; (6) the P_2O_5 taken up by plants is, however, greater than the H_2O available; (7) buckwheat roots in chernozem seem to be able to ext. more P_2O_5 from insol. phosphates than the other plants; (8) on podzolized soils the decreasing order of extg. P_2O_5 from insol. phosphates is: pea, buckwheat, flax, oats, mustard, sorghum; (9) fertilizing with KNO_3 doubled the activity of buckwheat roots in taking out P_2O_5 from insol. phosphates on chernozem and podzolized loam.

Assimilation of potassium, that had been absorbed by the soil, by roots of plants. P. V. Chirkov. *Izv. Akad. Nauk S.S.R., Ser. Biol.* 1951, No. 3, 100-10.—The percolation method used in sand cultures of oats, peas, and barley showed that for assimilation of K that had been absorbed by the soil it is unnecessary to maintain a phys. contact between the roots and the soil particles and exchanges (ionic) that occurs between the soil-bound inorg. salts and those in the percolating soil, serve to transfer K into soln. and make it available for the plant (of 209 mg. soil-absorbed K_2O about 200 mg. was assimilated by typical plants). The actual contact merely reduces the length of the essential diffusion path. The usual Pryanishnikov nutrient soln. was used, except for KCl, which was supplied as needed by the soil.

TITLE: Optical modulator based on the Michelson interferometer

SOURCE: Radiotekhnika i elektronika, v. 11, no. 8, 1966, 1516-1518

TOPIC TAGS: interferometer, optic modulator

ABSTRACT: Experiments with a Michelson-interferometer-type optical modulator are briefly reported. ADP-crystal (40 x 4 x 2-mm) cuts were used. The half-wave displacement was 820 v with one, and 410 v with two crystals. A control-voltage amplitude of 410 v produced a 100% modulation in the single-crystal scheme. The modulator passband, limited by the capacitance of electro-optical cells (28 pF), was about 100 Mc. The above interference modulator has these advantages: it

Card 1/2

UDC: 535.241.13

ACC NR: AP6027242

requires a much lower control voltage than other types; it does not require rigid monochromaticity of light (a radiation band of 100 Å is acceptable); its operation depends only slightly on the ambient-temperature variations. Disadvantages: high sensitivity to mechanical vibration; no use of TW line is possible. Orig. art. has: 2 figures and 8 formulas.

TITLE: Study of the Diffusion Porosity Occurring During
Distillation of Chromium From Single Crystals of
the Alloy 3V437B (EI437B)

PERIODICAL: Fizika metallov i metallovedeniye, 1961, Vol. 11,
No. 2, pp. 314 - 316

TEXT: As shown in other work by the authors (to be published
in Metallovedeniye i termicheskaya obrabotka metallov) diffusion
porosity occurs during distillation of chromium from the alloy
Х20Н80 (Kh20N80), whereby the pores are equally oriented
within the limits of 1 grain. By means of a method described
in an earlier paper (Ref. 3), the authors attempted to determine
the orientation of the pores in the initial stages of their
growth with respect to the crystal lattice of the alloy. Since
they did not manage to grow sufficiently large crystals of the
alloy Kh20N80 by recrystallisation, the authors used large
crystals obtained accidentally in scrap material from the
alloy EI437B; the composition of which is similar to that of

Card 1/6

S/126/61/011/002/023/025
E073/E335

Study of

Kh20N80. The single-crystal film which is required for investigating the pores by the method of small-angle X-ray scattering was obtained by mechanical grinding to a thickness of 150 μ , followed by electropolishing to a thickness of 60 μ . The electrolytic thickness-reduction did not ensure total removal of the work-hardened layer and the Laue pattern is blurred (Fig. 1 - pertaining to a single-crystal film of the alloy EI437B, the surface plane of which is near to the plane (100)). However, specimens produced from thicker sheet by electrolytic polishing were considerably nonuniform as regards thickness. The Cr distillation was effected in a quartz ampule (which was connected continuously to a pre-vacuum pump) at 1 330 $^{\circ}$ C for 2.5 hours. Shorter distillation times did not produce porosities. After terminating the distillation process, the specimen was rapidly thrown into the cooled part of the ampule to eliminate falling-out of the ordered phase. Some of the specimens crystallised during distillation and broke up into a number of small grains, whilst others remained single crystals. Curves of the drop in intensity of

the small-angle scattering as a function of the distance from the edge of the primary beam were plotted by photometering the X-ray diffraction patterns which were obtained by means of slot equipment built as described by Kratky (Ref. 4). The slot was located in differing crystallographic directions. Specimens were investigated, the surfaces of which were near to the plane (111) and (100). The photometric curves were standardised in such a way that the intensities at a distance of 1' from the edge of the primary beam were equal for all the X-ray diffraction patterns taken from the same specimen. Following that, lines of equal intensity were plotted in the polar coordinates (angles-intensity). The thus obtained graphs are plotted in Figs. 2a and b (curves of equal intensity of low-angle scattering in various directions: Fig 2a. - specimen surface near to the plane (111), 1, 2, 3, ...8 min; Fig. 2b - specimen surface near to the plane (100), 1, 2, 3, ...6 min). It can be seen that the intensity of low-angle scattering of X-rays drops more slowly for a specimen, the surface plane of which is near to the plane (111) if the

slot is in the direction [211] (corresponding to the photo-metering direction [110]). This means that in the direction [110] the dimension of the pore nucleus is at a minimum (Ref. 3). The anisotropy of the drop in intensity for specimens with the surface plane near to the plane (100) confirms these conclusions. It is pointed out that the anisotropy of low-angle scattering for the alloy EI437B is not as pronounced as it is for brass. This is attributed to the fact that the alloy is strongly contaminated with nonmetallic inclusions with irregular boundaries, which can be clearly seen in unetched polished cuts. They can serve as a basis for forming arbitrarily oriented pores.
