2096. THE ROLE OF ASSIMILATION AND ADAPTATION FACTORS IN THE DEVELOPMENT OF HETEROTRANSPLANTS - Die Rolle der Assimilations-Adaptationsfaktoren in der Entwicklung von Heterotransplantaten - Csaba, G., Histol.-Embryol. Inst., Med. Univ., Budapest - VIRCHOWS ARCH. PATH. ANAT. 1958, 331/6 (653-665) Illus. 6

In the behaviour of heterotransplants 3 phases can be distinguished: (1) the phase of traumatization and local disturbances in nutrition; (2) the phase of assimilation and adaptation; (3) the phase of immune reaction. Of the greatest importance for the fate of the transplant is the 2nd phase. This is shown by transplantsations of liver tissue into the anterior chamber of albino rats' eyes. In autotransplantations only the biliary ducts remained alive, and regeneration started from these. All transplants from homologous and heterologous mammals and fowls were destroyed and only transplants from fish and Triturus remained alive. Liver tissue cultivated on rat serum in tissue culture showed that all the tissues which remained alive in vivo survived also in vitro. It is therefore concluded that mainly all those tissues remain alive as transplants that are able to assimilate foreign proteins in vivo and in vitro. In the experiments of the author it is shown that the immune reactions are of less importance than assimilation and adaptation. The explanation for this fact is that tissues of phylogenetically lower forms have not only a higher ability for assimilation but also a lower antigen character.

Title : In Vitro Utilization of O₂ By Placentas Obtained in Normal and Pathological Pregnancies of Various Duration.

Orig Pub: Kiserl Orvostnd, 1956, 9, No 1, 48-53.

Abstract: The consumption of O₂ by placentas (P) obtained in the first trimester of normal pregnancies was of 6.5mm³ per 1 mg/hour. P. in pregnancies with late toxemia absorbed 3.5mm³. Under favorable hypoxic conditions (20% O₂) the consumption of oxygen was lower, and in P. of early pregnancy was 4.1, normal term. 2.3 and in preg-

CSADA, I.K.

Csada, I.K. On the magnetic effects of turbulence in ionized gases.
 Acta Phys. Acad. Sci. Hungar. 1, 235-246 (1952). (Russian summary)

The equations of hydromagnetics for an incompressible fluid are

$$(1) \frac{\partial u_i}{\partial t} + \frac{\partial}{\partial x_j} u_i u_j - \frac{\mu}{4\pi p} \frac{\partial}{\partial x_j} H_i H_j = - \frac{1}{\rho} \frac{\partial}{\partial x_i} \left(p + \frac{\mu |H|^2}{8\pi} \right) + v \nabla^2 u_i$$

and

$$(2) \frac{\partial H_i}{\partial t} + \frac{\partial}{\partial x_j} (H_i u_j - H_j u_i) = \eta \nabla^2 H_i \quad (\eta = 1/4\pi\sigma),$$

where μ and σ are the coefficients of magnetic permeability and electrical conductivity respectively and the rest of the symbols have their usual meanings. The author treats these equations in the manner in which the Stokes-Navier equation (i.e., eq. (1) with $H_i = 0$) has been treated in the past for defining the Reynolds stresses. Thus, writing

$H_i = \bar{H}_i + \delta H_i$ and $u_i = \bar{u}_i + \delta u_i$ where \bar{H}_i and \bar{u}_i are the mean values and δH_i and δu_i are the instantaneous fluctuations, we find that the averaged form of equation (2) is

CSADA, I.K.

p.2

$$(3) \quad \frac{\partial \bar{H}_i}{\partial t} + \frac{\partial}{\partial x_j} (\bar{H}_i \bar{u}_j - \bar{H}_j \bar{u}_i) = \eta \nabla^2 \bar{H}_i - \frac{\partial}{\partial x_j} (\delta_{H_i} \delta u_j - \delta_{H_j} \delta u_i).$$

With the further assumptions

$$(4) \quad \delta H_i = l_k \frac{\partial \bar{H}_i}{\partial x_k} \quad \text{and} \quad l_j \delta u_i = - \Lambda \delta_{ij}$$

where l_k is a vector defining the process associated with the concept of the "mixing length" and $\Lambda (= |l| \cdot |u|)$ is a constant, equation (3) becomes

$$(5) \quad \frac{\partial \bar{H}_i}{\partial t} + \frac{\partial}{\partial x_j} (\bar{H}_i \bar{u}_j - \bar{H}_j \bar{u}_i) = (\eta + \Lambda) \nabla^2 \bar{H}_i.$$

CSADA, I.K.

p.3

The mean magnetic intensity therefore satisfies an equation of the same form as (2) but with a different η ; in other words we may define an "eddy-electrical conductivity" just as an eddy-viscosity has been defined in the "heuristic" theories of turbulence.

TITLE: On the Structure of the General Magnetic Field of the Sun

PERIODICAL: Solnechnyye dannyye, 1956 (1957), Nr 6, pp 140 - 144 (Engl.)

ABSTRACT: The author explains his theoretical results on the structure of the sun's general magnetic field. An attempt is made to verify these results by the magnetograms published by Babcock (Babkok). The introduction of the potential vector produces equations of the type

$$\Delta x - \frac{x}{r^2 \sin^2 \theta} = \frac{1}{P} Q(x),$$

for corresponding components of velocity and the magnetic field; P - parameter (viscosity, resistance); Q(x) - linear operator. Taking into account the average electromagnetic parameters of the sun's surface, the author obtains for the vector-potential of the magnetic field the expression:

Card 1/3

20387

SOV/169-59-3-3021

On the Structure of the General Magnetic Field of the Sun

$$A \varphi = \frac{h_1 P_1^{(1)}}{r^2} + \frac{h_3 P_3^{(1)}}{r^4},$$

where P_{11} and P_{13} are adjuncted spherical functions. According to the author's investigations, the general magnetic field of the sun must comprise three systems of magnetic lines of force: the field of the dipole and of the equatorial region, perturbed by two systems of opposite-polarity fields near the poles. A possible explanation is given for such a structure of the sun's general magnetic field. The determination of the average, general magnetic field is carried out for verifying the theoretical results in view of Babcock's solar magnetograms. The planimetric processing of the registration of the field on the magnetogram for each track of 55 observation days facilitated the determination of the A and B coefficients in the expression for the field:

$$H_x = AP_2^{(1)} + BP_4^{(1)}$$

by the method of least squares. The mean values of the coefficients turned out to be $A = 0.028$ and $B = 0.155$ for the 1953/54 observation period.

SOV/169-59-3-3021

On the Structure of the General Magnetic Field of the Sun

Consequently, the sun's general magnetic field does not have a dipole, but an octupole character. The structure of the solar corona (the deviation of the polar rays from the direction of the lines of force of a central dipole) and the shapes of large prominences confirm the octupole character of the sun's general magnetic field.

ABSTRACT: On the basis of Babcock's magnetograms, the author discusses close to 350 recordings of the general solar magnetic field made from January 1953 to December 1954. The time integral is replaced by the arithmetic mean as the temporal mean value is calculated. The material is arranged into intervals of the

polar distance . The results are divided into terms which are and are not symmetrical to the equator, expressed by formulas and also given in figures in the original article. A model of the solar magnetic field is used in a theoretical discussion of the results. The actual observation is related to the poloidal and toroidal field components of the two-component system. The force lines of the toroidal field are situated below the photosphere; their fluctuating loops emerge above the photospheric level and are recorded as bipolar magnetic fluctuations. The results of calculations that also include limb darkening are given. The author concludes that the quadrupole terms are very small and play no part in the solar magnetic field, the dipole terms are of considerable magnitude, and that there are field strengths only in the polar areas. In the discussion following the article it is said that the author's observations are not in contradiction to the hypothesis that the general magnetic field of the sun is the mean of the total field of many local fields in both solar hemispheres. TITLE: Magnetohydrodynamic discussion of the expanding corona

SOURCE: Ceskoslovenska akademie ved. Astronomicky ustav. Publikace, no. 51, 1965. 3rd Consultation on Solar Physics and Hydromagnetics, Tatranska Lomnica, 13-16 October 1964, 133-136

TOPIC TAGS: solar corona, coronal temperature, isophote, coronal isophote, solar magnetic field, magnetohydrodynamics

ABSTRACT: The author considers the connection between a supposed expansion of the coronal gases and their temperature as a proof of expanding motion, and discusses velocity distribution in terms of temperature distribution. No complete picture of the distribution of coronal temperature is possible because only separate measure-

Card 1/2

L 46805-66

ACC NR: AT6020511

ments are available. The influence of density fluctuations which affect the isophotes is supposed to be very small, and an approximate analysis of coronal expansion in terms of coronal isophotes is possible. The author analyzes the velocity field on the assumption that the corona expansion is spherical; he considers two limiting cases and shows how the dipole varies with the expansion when the lines of force are right radial lines; and he discusses the plasma heating in the corona. The results obtained are then compared to Mr. Waldmeier's isophotes. Some similarity between the diagrams of the two authors and the coronal isophotes is found during minimum activity, but during maximum activity, there are well-defined deviations in the equatorial areas. The author concludes that in this phase, the loops of the toroidal lines play an essential role in the plasma-physics rate of coronal heating. In the discussion following the article, the author states that the boundary conditions for the system of magnetohydrodynamic equations considered are those applied in the whole magnetic theory. Orig. art. has: 4 figures.
