Title : Spirographic Examinations of Individuals with Heart  
Ailments.

Orig Pub : Fiziol. norm. si patol, 1956, 3, No 4, 471-478

Abstract : A study was made of the respiration of 16 patients with  
both compensated and decompensated heart diseases. A  
significant reduction was seen in maximal ventilation  
and respiratory reserve. Vital capacity was relatively  
slightly decreased (in the majority of patients there  
were no symptoms of congestion).

(Separation of paraffin hydrocarbons from heavy petroleum fractions by urea. V. Dinulescu, I. Irimescu, I. Irimescu, and A. Pounovic. Acad. Rep. Populare Romane, Studii Cercetari Chim. 2, 1971, 1-10. (French summary).) Several paraffin waxes, m. 50-70°, were recovered from heavy petroleum fractions (I) by means of complex formation with (NH<sub>2</sub>)<sub>2</sub>CO (II) or (NH<sub>2</sub>)<sub>2</sub>CS (III). The procedures used included: (1) reaction of an excess of solid II or III with I in the absence of diluents by using small amts. of an accelerator; (2) reaction as in procedure 1 but in the presence of solvents acting as accelerators; (3) reaction of an aq. soln. of II or III with a soln. of I in suitable solvents. The following solvents were used: MeOH, EtOH, iso-PrOH, iso-BuOH, a mixt. of amyl alcoh., Me<sub>2</sub>CO, and MeCOEt. With the exception of MeOH, all solvents required small amts. of H<sub>2</sub>O to be effective as catalysts. Mixts. of 1.5 parts ligroine and 0.5 parts of the solvents listed were equally suitable. Min. reaction time in all cases was 30 min. The cryst. products were recovered from the complex by washing with H<sub>2</sub>O at a temp. above the m.p. of the paraffins and decantation or extrn. with CCl<sub>4</sub> or ligroine b. 90-110°. The yields obtained were almost quant. Gerard Aufleger

DINULESCU, I G

Isomerization of 1,2-*trans*-dibromocyclohexane under the influence of anhydrous aluminum bromide. Costin D. Nenitrescu and Ilie G. Dinulescu. *Acad. rep. populare Romane, Studii cercetari chim.* 1, 7-14 (1959).—Hydrogen migration in dihalocyclohexanes was investigated following previous work (C.A. 37, 3740<sup>a</sup>) on H<sup>+</sup> migration in Friedel-Crafts type reactions. Present work concerned behavior of dibromocyclohexanes in the presence of anhyd. AlBr<sub>3</sub> at 0° in a nonpolar inert medium, CS<sub>2</sub>. 1,2-*trans*-Dibromocyclohexane isomerized to yield 70-87% isomeric product contg. approx. 25% cryst. *trans*-1,4-C<sub>6</sub>H<sub>10</sub>Br<sub>2</sub> and 75% liquid, mostly 1,3-C<sub>6</sub>H<sub>10</sub>Br<sub>2</sub> (probably *trans*), dissolving partly the 1,4-isomer. No residue of initial 1,2-isomer was detected. The same final equil. compn. was obtained with *trans*-1,1-C<sub>6</sub>H<sub>10</sub>Br<sub>2</sub>, 1,3-C<sub>6</sub>H<sub>10</sub>Br<sub>2</sub> (probably *trans*), and *trans*-1,4-C<sub>6</sub>H<sub>10</sub>Br<sub>2</sub> as initial isomer. The reaction conformed to carbocation formation, under influence of the electrophilic catalyst, followed by H<sup>+</sup> migration. Similar work with a polar medium, HBr, gave different results (cf. Coering and Sims).

TITLE: Some remarks on the date of the actual solar activity minimum

SOURCE: Ceskoslovenska akademie ved. Astronomicky ustav. Publikace, no. 51, 1965. 3rd Consultation on Solar Physics and Hydromagnetics, Tatranska Lomnica, 13-16 October 1964, 58-61

TOPIC TAGS: sunspot, sunspot cycle, sunspot area, solar activity

ABSTRACT: The author discusses the method used to find the date of actual minimum solar activity for cycle no 20, which began on 28 August 1963, (rotation 1471) by a pore which appeared in the latitude of +34°. The ratio of the number of new groups which appeared per rotation in the new and old cycles increases in value

Card 1/3

L 46814-66

ACC NR: AT6020498

beginning with rotations 1479 to 1482, with groups from the new cycle predominating in relation to the groups of the old cycle in rotations 1482 and 1483. The separation of the spots into cycles was made using the latitudes as criterium. It was not possible to use the magnetic separation criterium due to incomplete data. The relative Wolf (R) number decreased in 1964, to a minimum in July, which had the most days with a zero Wolf number. The correct monthly mean areas, according to another work, [Fenomeni Solari, circolare No. 73—80, Osservatorio Astronomico di Roma, 1964] also show July as the month with the smallest area: eight-millionths of the hemisphere. Calculations and conclusions based on Giovanelli's data [Giovanelli, R. G. The Observatory, No. 939, p. 57—66, April 1964] show that when the cycles 19 and 20 are superposed, the latest spots from the old cycle will appear in the interval of rotations 1502 to 1508, and the two curves will intersect at the interval of rotations 1486 to 1490, because the first group of spots from the new cycle appeared during rotation 1471. Determination of the moment of intersection of the decay and rise curves for the present cycle using the diagram of Giovanelli completed with up-to-date values for the new cycle, shows the intersection point to be at rotation 1484. On the

2/3

L 46814-66

ACC NR: AT6020498

basis of comparisons of minimum solar activity for cycles 13-19 with data produced by the intersection of decay and rise curves, rotations 1481 to 1488 are found for the present minimum. The table included in the original text shows rotation 1483 to be that which up to now had the smallest value for relative Wolf number. The moment of the minimum will be obtained from the mean of the relative numbers in the period of minimum activity. Orig. art. has: 5 tables, and 1 figure. [GC]

"The Compression and Rupture of the Umbilical Cord During Childbirth"

Belgrade, Medicinski Glasnik, Vol 17, No 5, May 1963, pp 190-192.

Abstract: [Authors' Serbocroatian summary modified] The most frequent causes of trouble with the umbilical cord in childbirth are sideways or crosswise positions in the womb and pronounced cephalopelvic disproportion. Childbirth must be completed as soon as possible if the umbilical cord is compressed or broken, by operation if necessary, unless the infant is already dead. The authors describe their experiences with 30 such cases out of 12,524 births at their clinic between 1957 and the end of May 1962.

AUTHORS: Dinzburg, B. N., Safray, B. A., Candidate of Technical Sciences

TITLE: A New Active White Filling Material From Waste of Super-phosphate Production

PERIODICAL: Khimicheskaya promyshlennost', 1960, No. 1, pp. 76 - 77

TEXT: The Institute mentioned under Association together with a number of other institutes worked out the technique for the production of silica gel (under the name of "Belaks") from waste of super-phosphate production nonutilized at present, which is to be used as white filling material for high-quality colored rubber. The production of silica gel is divided into 4 principal stages: separation of silica gel from silicofluoric acid on rubber-covered filtering centrifuges, washing of silica gel, drying, milling, and sifting. The properties of the "Belaks" are compared with those of the powdered silica gel in Table 1. The mean comparative values of the rubber types "Ekstra" and "Progress" filled with powdered silica gel and Belaks (Table 2), the results of the aging tests of the 2 types

Card 1/2

A New Active White Filling Material From Waste of Super-phosphate Production S/064/60/000/01/18/024  
B022/B008

of rubber mentioned (Table 3) as well as the results of the resistance-to-frost tests of porous rubber types filled with powdered silica gel and Belaks (Table 4) are given. It appears from the results that the properties of the active white filling material are equivalent to those of powdered silica gel. The industrial properties of "Belaks" were checked industrially. The Kalininskiy kombinat "Iskoz" (Kalinin Kombinat "Iskoz" (Synthetic Leather)), the kombinat v Maardu (Kombinat at Maardu), the Kiyevskiy regeneratno-rezinovyy zavod (Kiyev Rubber Regenerating Plant), and the Vinnitskiy superfosfatny zavod (Vinnitsa Super-phosphate Plant) are mentioned. There are 4 tables.

AUTHORS: Kogan, L. M., Safray, B. A., Dinzburg, B. N., Polinskiy, S. L.

TITLE: New incombustible plasticizers of PVC

PERIODICAL: Plasticheskiye massy, no. 3, 1961, 67-69

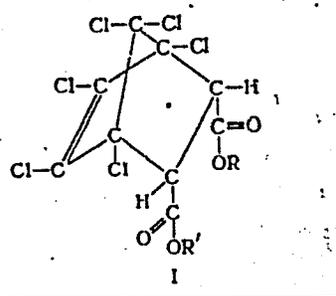

TEXT: As is known, the compatibility with PVC rises with the polarity of the plasticizer, whose efficiency is determined by the aliphatic and also by the cyclic part of its molecule. Esters with several chlorine atoms in the molecule are of interest in this connection. Direct chlorination of the ester or of the corresponding acid is, however, difficult; the synthesis of these compounds is simpler from compounds containing chlorine in the molecule, particularly from acids of polycyclic structure with several chlorine atoms, and from aliphatic alcohols. As PVC plasticizers, the authors synthesized and tested the diesters of 1,4,5,6,7,7-hexachloro bicyclo-(2,2,1)-5-heptene-2,3-dicarboxylic acid (so-called chlorendic acid) and of aliphatic alcohols. They called these compounds dialkyl chlorendates. Dialkyl chlorendate molecules have the following structure:

Card 1/6

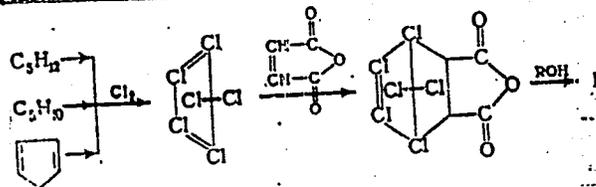

New incombustible plasticizers of PVC

20489

S/191/61/000/003/013/015  
B124/B203

The synthesis of such a compound can be represented as follows:

Chlorine and petroleum hydrocarbons are initial substances for the new

Card 2/6

20489

S/191/61/000/003/013/015  
B124/B203

New incombustible plasticizers of PVC

plasticizers. The authors tested diesters with the same aliphatic radicals containing 1-8 carbon atoms. Tables 1 and 2 give the results of determination of the properties of products obtained from PVC with esters of chlorendic acid, i.e., dimethyl ester of chlorendic acid (C-561) and dibutyl ester (C-564) alone and combined with dibutyl phthalate (DBP). The initial material used was PVC resin of the type ПЭ-1 (PF-1) (according to ГОСТ 3119-46 (GOST 3119-46)) with a viscosity of the 1% solution in dichloro ethane of 2.3 cp, an ash content of 0.15%, a destruction temperature of 165°C, a thermostability of 25 min, a basicity of 0.04%, traces retained on sieve- 015 (GOST 6613-53). Table 3 gives the results of tests made on plasticized PVC films. The results reveal that the new synthetic plasticizers are superior to DBP with respect to incombustibility, higher aging resistance, and reduced stickiness. The authors thank Professor A. A. Berlin for his help. There are 3 tables and 10 references: 9 Soviet-bloc and 1 non-Soviet-bloc.

TITLE: Use of condensation resins in the preparation of rubber products. Report No. 2

SOURCE: Moscow. Vsesoyuznyy nauchno-issledovatel'skiy institut plenochnykh materialov i iskusstvennoy kozhi. Nauchno-issledovatel'skiy trudy, no. 19, 1962, 3-20

TOPIC TAGS: synthetic rubber, butadiene styrene rubber, condensation resin, vulcanizate, thermosetting resin, phenol formaldehyde resin, filler, resite stage

ABSTRACT: The authors studied the properties of vulcanizates of the butadiene-styrene rubber SKS-30, prepared by using thermosetting rubber-resin mother mixtures. The influence of phenolic resins in the absence of fillers and the effect of fillers on rubber strengthened by phenol-formaldehyde resins were examined. The work also involved a study of the possible mechanism of strengthening of butadiene-styrene rubbers by phenolic resins when rubber-resin mother mixtures are prepared. The resin employed was the phenol-aniline-formaldehyde resol 211. Mechanical blending of rubber SKS-30 with the resin at a temperature sufficient for conversion of the resin into the resite stage causes the formation of various rubber-resin structures having diverse physico-mechanical properties. The study of the interaction between

Card 1/4

I 52355-65

ACCESSION NR: AT5012716

the rubber and resin has led to the hypothesis that, initially, part of the linear resin on conversion from the resol stage to the resite stage in the rubber medium combines with the latter, forming a graft polymer in which the length of the side chain is considerably shorter than that of the main macromolecule. This is represented by Fig. 1 of the Enclosure. As the resin content increases, a simultaneous formation of type A structures and isolated particles of resite in the rubber mass takes place, and the type A structures may link up with the resite particles to form a rubber-resin structure of type B (see Fig. 2 of the Enclosure). Orig. art. has: 19 figures and 4 tables.

TITLE: Modification of rubbers by thermoreactive rubber-resin master batches

SOURCE: Kauchuk i rezina, no. 6, 1963, 10-13

TOPIC TAGS: thermoreactive phenolic resin, modification of rubber, rubber-resin master batches, bakelite resin

ABSTRACT: A method was developed to reinforce nonpolar rubbers by the incorporation of comminuted bakelite resin into a film of rubber on heated rollers, beginning at 40-60C and ending at over 140C. When the mixture was compounded of 100 parts rubber, 30 parts bakelite, and 30 parts powdered silica gel, the optimal duration of the process was 10-25 minutes. The resulting product is a solid nonsticky mass which can be handled like ordinary rubber and can be used for various kinds of rubber compounds. It keeps for several days but must be reworked if used after prolonged storage. The most effective bakelite type resin

Card 1/2

L 13537-63

ACCESSION NR: AP3003287

is the one containing an amino group. The new varnish resins are effective irrespective of composition, providing hexamethylenetetramine was used as the polymerizing agent. The obtained master batches produced colored vulcanizates with satisfactory strength, as well as higher elasticity and resistance to freezing. Orig art. has: 1 picture, 2 charts, and 1 table.

TITLE: Deformation-elasticity properties of porous vulcanized rubbers from rubbers combined with thermoreactive resins

SOURCE: Kaucuk i rezina, no. 1, 1964, 8-10

TOPIC TAGS: vulcanized rubber, porous vulcanized rubber, synthetic resin, thermoplastic resin, thermoreactive resin, polystyrene, phenolic resin, porophore, compression deformation, compression elasticity, phenol formaldehyde resin

ABSTRACT: The present study is a continuation of earlier work, by the authors on the advantages of using thermoreactive synthetic resins rather than thermoplastic resins in the production of porous rubber master batches (Legkaya prom., No. 9, 26, 1958). Under investigation were cylindrical samples, 32 mm in diameter and 20-25 mm high, of SKS-30 rubber, containing 30 parts by weight of either phenol-anilineformaldehyde resin 211 or polystyrene, and 30 parts kaolin, as well as the other usual components of rubber compounds, and the porophore ChKhZ-5. These rubber mounts were subjected to compression deformation studies which revealed that up to a deformation of 50% there existed an approximate linear relationship

Card 1/2

ACCESSION NR: AP4015073

between the extent of rubber deformation and the magnitude of the load. From there on (up to a deformation level of 75) a sharp increase in the load magnitude was required, and beyond 75% the deformation of the samples was no longer affected by an increased load. It was also found that the residual compression of rubbers containing phenolanilineformaldehyde resin was 2-3 times smaller than in the samples containing polystyrene and that the elasticity of the former was also higher, which was attributed to its greater hardness. A study of the behavior of the two samples within a temperature range up to 80C revealed that while the polystyrene-porous rubber exhibited a sharp upturn in the compression deformation curve at the stage of 75% shrinkage, the corresponding curve for the phenolformaldehyde specimen remained practically unaffected. The authors attribute this effect to the thermoreactivity of the phenolformaldehyde resin, which imparts thermostability to the rubber compound. Orig. art. has: 6 charts and 1 table.

TITLE: Properties of vulcanizates from NBR rubbers combined with thermosetting resins

SOURCE: Kauchuk i rezina, no. 7, 1964, 11-15

TOPIC TAGS: NBR rubber, phenolic resin, synthetic rubber, novolak resin, resol resin, thermosetting resin, rubber SKN-18, rubber SKN-26, rubber SKN-40, NBR vulcanizate property, phenolic resin effect, urotropin effect, thermosetting master batch method, vulcanizate transparency

ABSTRACT: NBR rubbers SKN-18, SKN-26 and SKN-40 were combined with novolak resins #18, 15 and 17 or resol resins #76, 118, 214, 220, 236 and Bakelite A (100 parts by weight NBR rubber, 2 parts stearin, 5 parts zinc oxide, 2 parts sulfur, 3.5 parts Captax, 3 parts hard resin; urotropin, 0-15 parts by weight of resin) on 200 x 450 mixing rolls (friction 1.33), using standard (20min., roll temp. 30-50C) or thermosetting master batch

Card 1/3

ACCESSION NR: AP4042338

( 20 min. , 150C) methods. The vulcanization temperature was 155C. The vulcanizates were analyzed to determine the effects of the various resins on their properties and the comparative effectiveness of the two different methods. Results are tabulated and graphed (see Enclosure) and indicate that the physical and mechanical properties were improved substantially by addition of phenolic resins and urotropin as the curing agent. Transparent vulcanizates can be obtained with optimal proportions (10 parts by weight to 100 parts of resin) or urotropin. The thermosetting master batch method significantly increased the effectiveness of the use of phenolic resins in NBR rubbers, especially in increasing the strength and cold resistance of the vulcanizates. Orig. art. has: 4 graphs and 4 tables.

TITLE: The mechanism of rubber reinforcement using thermosetting resins

SOURCE: Kauchuk i rezina, no. 3, 1965, 12-15

TOPIC TAGS: rubber, thermoreactive phenolic resin, resin, strengthening

ABSTRACT: The article presents some results of an investigation of the mechanism of the interaction of butadiene-styrene rubbers with phenol-formaldehyde resins. In studying this mechanism it must be kept in mind that phenol resins and rubber are extremely multifunctional with respect to their reactivity; therefore, it may be assumed that various rubber-resins are formed. It had previously been established that there is in the oxidation products of rubber a considerable number of carbonyl, caroxyl, and other oxygen-bearing groups which apparently can affect the nature of the interaction of rubbers with phenol-formaldehyde resin. A number of samples of SRS-30 rubber were prepared with different degrees of thermooxidative rolling, and their content of peroxide, aldehyde, and carboxyl groups was determined. Electron microscope analysis showed that the particles of resin joined in

23.  
22  
B

Card 1/3

L 48314-65

ACCESSION NR: AP5008128

complexes were spherical formations which could be broken down into two groups: a first group consisting mainly of particles with clear-cut outlines and sizes ranging from 0.15-0.20 microns, and a second group of particles with blurred edges joined in aggregates. The particles of the first group probably do not contain chemically combined rubber whereas the particles of the second group are more complex formations. Based on modern reinforcement theory and considering the data obtained it can be concluded that in the modification of butadiene-styrene rubber with phenol resins by the method of "thermosetting rubber-resin master batches," complex thermomechanicochemical processes occur which lead to the formation of various rubber-resin structures. A new modified rubber (type A) obtained as a result of the interaction of rubber with small additions of phenol resins is reinforced with specific rubber-resin fillers (types B and C) which are highly active because of the similarity of the nature of their surfaces and their ability to form high developed latticed structures. Orig. art. has: 6 figures, 1 table.

✓  
 Irreversible reciprocal system of sodium and lithium chromates and hydroxides. V. A. Reshtnikov and G. G. Drogotnov (Institute of Med. Inst., Soviet State Obit. Inst., Moscow, U.S.S.R.), *J. S.S.R. Chem.*, 1, 112-26 (1959). -- The reciprocal system Li, Na || OH, CrO<sub>3</sub> was deduced from 2 diagonal and 18 internal cross sections and the 4 binaries. The data are given in 24 tables and 11 diagrams. The binaries Li(OH)-Na(OH) (a) and Li(OH)-Li<sub>2</sub>CrO<sub>4</sub> (b) were detd. for the first time; the binaries Na(OH)-Li<sub>2</sub>CrO<sub>4</sub> (c) and Li<sub>2</sub>CrO<sub>4</sub>-Na<sub>2</sub>CrO<sub>4</sub> (d) were redetd. In a there are 3 transition points at 254, 238, and 299° with 57, 5, and 64.5 mol. % NaOH; 2 compds. of uncertain compn. In b there are 2 congruent compds. 4 LiOH·3Li<sub>2</sub>CrO<sub>4</sub> and LiOH·Li<sub>2</sub>CrO<sub>4</sub>, m.ps. 430 and 460°, resp.; a eutectic at 311° and 2 transition points at 427 and 440° with 45, 64, and 78% Li<sub>2</sub>CrO<sub>4</sub>. In c the polymorphic transition of Li<sub>2</sub>CrO<sub>4</sub> at 440° is underscored; a

congruent compd. Li<sub>2</sub>CrO<sub>4</sub>·Na<sub>2</sub>CrO<sub>4</sub>, m. 412°, and 2 transition points at 353 and 404° with 31.5 and 18.5% Na<sub>2</sub>CrO<sub>4</sub>. In d there are 4 transition points at 304, 300, 380, and 415° with 4.6, 8.0, 16, and 63% Na<sub>2</sub>CrO<sub>4</sub>; 2 compds. 4NaOH·Na<sub>2</sub>CrO<sub>4</sub> and 2NaOH·Na<sub>2</sub>CrO<sub>4</sub>, m.ps. 348 and 423°, resp. The chromate branch above 580° was not investigated. The stable diagonal Li(OH)-Na<sub>2</sub>CrO<sub>4</sub> (I) is characterized by a series of solid solus. with a min. m.p. at 410° (this contradicts established rules of isomorphism and further investigations will be made). The unstable diagonal Na(OH)-Li<sub>2</sub>CrO<sub>4</sub> is an irregular curve with 3 branches intersecting at 300, 292, 285, 321, 243, 340, and 440°. The reaction of the system is expressed by expression 2NaOH + Li<sub>2</sub>CrO<sub>4</sub> = 2LiOH + Na<sub>2</sub>CrO<sub>4</sub>; ΔH = -14.5 kcal. The equl. is shifted toward the stable pair at the left, which justifies the classification of this reciprocal system as irreversible. In the stable triangle Li(OH)-Na(OH)-Na<sub>2</sub>CrO<sub>4</sub> there are 3 fields of crystn.: LiOH·NaOH, 4NaOH·Na<sub>2</sub>CrO<sub>4</sub>, and 2NaOH·Na<sub>2</sub>CrO<sub>4</sub> with 0.47, 1.44, and 4.68% of the projected area, resp.; 3 transition points at 228, 270, and 304°, and a eutectic at 221°. In the stable triangle Li(OH)-Li<sub>2</sub>CrO<sub>4</sub>-Na<sub>2</sub>CrO<sub>4</sub> there are 6 fields of crystn.: 4LiOH·3Li<sub>2</sub>CrO<sub>4</sub>, LiOH·Li<sub>2</sub>CrO<sub>4</sub>, Li<sub>2</sub>CrO<sub>4</sub>·Na<sub>2</sub>CrO<sub>4</sub>, 4LiOH·Na<sub>2</sub>CrO<sub>4</sub>·3Li<sub>2</sub>CrO<sub>4</sub>, and the field Li<sub>2</sub>CrO<sub>4</sub> which is divided by the line of polymorphic transformation into α and β-Li<sub>2</sub>CrO<sub>4</sub> (the resp. areas are: 1.43, 1.23, 3.80, 0.16, 2.23, and 4.35%); and 6 eutectics at 342, 317, 347, 342, 337, and 340°.

USSR/Chemistry - Alkali metals, Periodic System

"The Classification of Mutual Systems Formed of Alkali Metals," G. G. Diugenov, Irkutsk Med Inst., Chair of General and Analytical Chemistry Zhur Obshch Khim, Vol 23, No 1, pp 20-24

The thermal effect of mutual systems formed by alkali metals changes periodically within the limits of groups in Mendeleev's system. The mutual systems possible for alkali metals are classified into 10 types, whereby the type of the mutual system is determined by its position in a table, made up on the basis of the relative proximity of the alkali metals in the periodic table. The less the radius of the anion, the greater the deviation from equilibrium in mutual systems.

DIJGENOV, G. G.

The ternary system of the acetates of lithium, sodium, and potassium. G. G. Diogenov, *Zhur. Neorg. Khim.* 1, 1551-6 (1957). The system LiOAc-NaOAc-KOAc is characterized by 3 double salts, 4LiOAc.NaOAc (I), 2LiOAc.KOAc (II), and LiOAc.KOAc (III), occupying, resp., 4.3, 22.5%, and 4.84% of the triangular phase diagram. The eutectic points, temp., compn. (m.m. %), and stable solid phases are, resp.: E<sub>1</sub>, 167°, LiOAc 87.0, NaOAc 34.0, KOAc 9.0, NaOAc + I + II; E<sub>2</sub>, 167°, LiOAc 22.0, NaOAc 27.0, KOAc 41.0, NaOAc + II + III. Similarly the peritectic point data are: P<sub>1</sub>, 215°, LiOAc 78.0, NaOAc 9.0, KOAc 13.0, LiOAc + I + II; P<sub>2</sub>, 159°, LiOAc 31.0, NaOAc 25.0, KOAc 44.0, KOAc + II + III. LiOAc undergoes  $\alpha \rightarrow \beta$  transformation at 200°, melts at 291°, and is stable in the liquid phase up to 300°.  $\alpha \rightarrow \beta$  transformations were observed in NaOAc and KOAc at 15-20° below their respective m.ps. C. H. Fuchsman.

TITLE: The Reciprocally Reversible System of the Acetates and Iodides of Sodium and Potassium (Obratimo-vzaimnaya sistema iz atsetatov i iodidov natriya i kaliya)

PERIODICAL: Nauchnyye doklady vysshey shkoly, Khimiya i khimicheskaya tekhnologiya, 1958, Nr 3, pp. 413 - 416 (USSR)

ABSTRACT: The reciprocal system Na, K || CH<sub>3</sub>COO, J was investigated by the visual-polythermal method. (vizual'no-politermicheskim metodom). Since the melting points of NaJ and KJ are comparatively high, only that range of the system which is close to the binary system CH<sub>3</sub>COOK - CH<sub>3</sub>COONa was investigated. The authors investigated; The binary system CH<sub>3</sub>COONa - NaJ (Table 1, Diagram 1). It has a eutectic point at 23 mole% NaJ. The sodium acetate has two polymorphous modifications with the transformation point at 326°C. The binary system CH<sub>3</sub>COOK - KJ (Table 1, Diagram 1) was also investigated. It is analogous to the former system in many respects. Potassium acetate has two modifications, its point of transformation being at

and Iodides of Sodium and Potassium

SOV/156-58-3-3/52

296°C. The binary system  $\text{CH}_3\text{COONa} - \text{CH}_3\text{COOK}$  (Table 2, Diagram 1) and the binary system  $\text{NaJ} - \text{KJ}$  have been investigated by a number of authors. The diagonal sections were also investigated below the temperature of decomposition of the acetates (360° - 380°):  $\text{CH}_3\text{COONa} - \text{KJ}$  (Table 1, Diagram 2A),  $\text{CH}_3\text{COOK} - \text{NaJ}$  (Table 1, Diagram 2A). In addition, 12 different sections were investigated (Tables 2, 3 and 4, Diagrams 2B, 2C and 3). Diagram 4 shows the projection of the liquidus system  $\text{Na}$ ,  $\text{K} \parallel \text{CH}_3\text{COO}$ ,  $\text{J}$  to the ground square; the single sections are discussed briefly. The eutectic point is at 220°, 38,5%  $\text{CH}_3\text{COONa}$ , 8%  $\text{NaJ}$  and 53,3%  $\text{CH}_3\text{COOK}$ . Another triple point is a point of passage (prokhodnaya tochka): 301°, 74%  $\text{CH}_3\text{COONa}$ , 13%  $\text{CH}_3\text{COOK}$  and 13%  $\text{NaJ}$ . There are 4 figures, 4 tables, and 7 references, which are Soviet.

TITLE: A Non-Reversible Exchange System of Acetates and Nitrates of Sodium and Rubidium (Neobratimo-vzaimnaya sistema iz atsetatov i nitratov natriya i rubidiya)

PERIODICAL: Zhurnal neorganicheskoy khimii, 1958, Vol 3, Nr 7, pp 1644-1649 (USSR)

ABSTRACT: The exchange system Na, Rb || CH<sub>3</sub>COO, NO<sub>3</sub> was investigated by the visual polythermal method. First the two-component systems CH<sub>3</sub>COONa-CH<sub>3</sub>COORb and CH<sub>3</sub>COORb-RbNO<sub>3</sub> were investigated. In the system CH<sub>3</sub>COONa-CH<sub>3</sub>COORb an incongruent compound is formed (formula CH<sub>3</sub>.COONa.3CH<sub>3</sub>COORb) with a melting point at 180° C. In the second system a congruent compound (formula RbNO<sub>3</sub>.2CH<sub>3</sub>COORb) with a melting point at 202° C is formed. Rubidium acetate, like lithium acetate, sodium- and potassium acetate, has two polymorphous modifications with a point of transformation at 215° C. The melting point of rubidium acetate is increased in the presence of other salts from 236° C to 300° C. There are 3 figures,

TITLE:

Metallurgy of the Future (Metallurgiya budushchego)

PERIODICAL:

Tekhnika molodezhi, 1959, <sup>21</sup>Nr 2, pp 2-4 (USSR)

ABSTRACT:

In this popular-scientific article the author writes about the possibilities of development of metallurgy. The traditional metals have gained more and more importance in modern times. Their extraction increases steadily, and their range of application is steadily extended. For economic reasons, the ores rich in metal are preferred for the extraction. One should, however, consider already now that such ores are exhausted with time, and one will be obliged to use less abundant ones. However, the technical development will ensure that the extraction will be productive if the production costs are reduced and the mineral raw materials are fully worked up, reducing the production waste to a minimum. Such manufacture requires a new technology. First of all, it must endeavor to complete the enrichment processes, and to substitute the pyrometallurgic (high temperature) processes by hydrometallurgic ones. But this

Card 1/3

Metallurgy of the Future

SOV/29-59-2-2/41

is only promising if the required solvents are cheap, i. e. if they can be produced during the process. Further, the co-operation of metallurgists and biologists should be considered. It is known that some elements including metals are stored up by plants. Such processes are steadily taking place in nature, but are poorly investigated and have not found practical application yet. One could describe biometallurgy as a step backward, but also this direction is quite real and might be usefully applied, though not generally, but for some rare metals with a scattered occurrence. For 60 years, the conversion process of elements has been known. These processes which had been detected in natural radioactive elements are today taking place on a large scale in atomic piles. It cannot be anticipated what part the conversion of elements will play in the metallurgy of the future. The solution of this problem is reserved to the 21st century. But it is quite as real as the cosmic flight or a peaceful application of thermonuclear energy. Scattered and rare elements can be obtained from sea water and hydrometallurgic solutions by means of filtration with ionites. In this respect, the sea water is particularly interesting as it contains not less than

Metallurgy of the Future

SOV/29-59-2-2/41

50 elements in a dissolved state, and its stores are practically inexhaustible. The interior of the earth has been poorly investigated. The technical development makes it probable that one will also penetrate great depths and will possibly discover abundant metal deposits. History teaches us that metallurgy underwent many transformations in the course of time. For thousands of years, fire has been used for the extraction of metals. Today, some other methods are coming to the foreground. Still, it will take some considerable time until one will develop a really universal and economical method. In modern times, metals have greatly been suppressed by synthetic materials. But they will never lose their importance because of their irreplaceable properties. Industry puts up very distinct demands to metals and alloys which titanium meets in a high degree. But for the time being, its extraction is rather complicated. Such metals as vanadium, niobium, zirconium, tantalum, molybdenum, tungsten, and some other elements of the secondary groups of the periodic system also correspond to the same demands. Technical progress, however, suggests that the difficulties in their extraction will be eliminated, and they may be called the metals of the future. There are 3 figures.

TITLE: The Ternary Reciprocal System of the Acetates and Nitrates  
of Potassium and Cesium

PERIODICAL: Zhurnal neorganicheskoy khimii, 1960, Vol. 5, No. 9,  
pp. 2084-2087

TEXT: This paper continues the investigations (Refs. 1-3) on the reaction taking place between the acetates and nitrates of alkali metals in melts. The present experiments were conducted according to the polythermal method, applying a Chromel-Alumel thermocouple and a millivoltmeter. Table 1 gives the melting point of the initial substances. System  $\text{CH}_3\text{COOK-KNO}_3$  has already been described (Ref. 2), while system  $\text{CH}_3\text{COOCs-CsNO}_3$  was investigated for the first time (Table 3, Fig. 2), and it was found that a eutectic forms with 25%  $\text{CsNO}_3$  and a melting point at  $142^\circ\text{C}$ . System  $\text{CH}_3\text{COOK-CH}_3\text{COOCs}$  (Table 1, Fig. 2) has a eutectic with a melting point

at 132°C at a CH<sub>3</sub>COOK content of 28.5%. System KNO<sub>3</sub>-CsNO<sub>3</sub> (Table 1, Fig. 2) ✓  
forms continuously solid solutions with a minimum at 220°C, and system  
NaNO<sub>3</sub>-CsNO<sub>3</sub> forms a eutectic at 47% CsNO<sub>3</sub> with a melting point at 177°C

Table 2 gives a survey of binary systems of the alkali- and alkali-earth  
nitrates with publication data, and mentions the following scientists:  
V. P. Blidin, P. I. Protsenko, N. N. Volkov, G. P. Tumash, G. A. Bukhalova,  
M. L. Sholokhovich, A. G. Bergman, N. A. Pushin, M. Rodonovich, M. N.  
Zakhvalinskiy, N. M. Vaksberg, V. G. Gimel'shteyn, N. P. Popovskaya. Table  
4 gives data on the composition, the phase equilibrium, and the correspond-  
ing melting point for the ternary system. There are 4 figures, 4 tables,  
and 16 Soviet references.
