with active surface of 15·15 mm is less than 20μ , i.e., it is small as compared to the total dimensions of the region of the microsource. In conclusion, it is stated that the part of the region of the microsource in which maximum intensity of the reflected radiation is observed, was $20\cdot500\mu$ under the experimental conditions described. The use of a bent quartz crystal in the X-ray spectrograph of the scanning microanalyzer is difficult due to the infinitesimal character of the region of the microsource. An increase of this region by using larger active surfaces of the crystal leads to a decrease in the resolution and the sensitivity of the instrument. Also the quality of the circular curvature of the crystal greatly influences the dimensions of the microsource. The author thanks I. B. Borovskiy for interest and discussion. There are 5 figures and 3 references: 2 Soviet-bloc and 1 non-Soviet-bloc. The reference to an English-language publication reads as follows: Mulvey T., J. Sci. Instr., 36, 150 (1959).

TITLE: A two-channel X-ray microscope

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya fizicheskaya,
v. 27, no. 3, 1963, 427-429

TEXT: The design of a new two-channel X-ray microanalyzer which comprises two X-ray spectrometers with linear crystal displacement is described. The instrument makes it possible to investigate the fine structure of X-ray emission spectra, and also to analyze two elements simultaneously. Focusing is carried out in both spectrometers by the Kapitsa - Johann method. The radius of curvature of the crystal is 500 mm. The vacuum spectrometer is intended for use at Bragg angles of 25 to 45°, and the non-vacuum spectrometer for angles between 25 and 60°. The vacuum spectrometer and the specimen chamber can be pumped down to $1-5 \cdot 10^{-5}$ mm Hg, either simultaneously or independently. The direction of the radiation to be analyzed is constant throughout the total range of reflection angles.

S/0048/64/028/005/0872/0876

AUTHOR: Ditsman, S.A.

TITLE: Concerning the optimum location of an x-ray source in an x-ray spectrograph
Report, Seventh Conference on X-Ray Spectroscopy held in Yerevan 23 Sep-1 Oct 1963

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v.28, no.5, 1964, 872-876

TOPIC TAGS: x-ray spectrograph, x-ray technique, microanalysis

ABSTRACT: The author has previously shown that in an x-ray spectrometer employing Kapitsa-Johann focusing, the intensity of the spectrum from a point source decreases rapidly as the source is moved away from the Rowland circle (Izv.AN SSSR,Ser.fiz., 25,923,1961). In the present paper this conclusion is confirmed experimentally and with calculations. The Ni K radiation of a 10 micron diameter source was first examined with the source on the Rowland circle of a 50 cm radius quartz crystal, and then with the source at the same distance from a plane quartz crystal. The ratio of the intensities of the spectra was found to be equal to the ratio of the areas of the crystal participating in their formation. This equality is assumed to hold generally, and with its aid the intensity of the spectrum of a point source formed by

Card 1/3

ACCESSION NR: AP4038781

a spectrograph with Kaptisa-Johann focusing is approximately calculated as a function of the distance of the source from the Rowland circle. The relation thus found is expressed graphically for particular geometric conditions. The calculated intensity decreases rapidly as the source moves away from the Rowland circle. This theoretical relation was verified by measurements of the intensity of the Cu K α_1 line from a 5 micron diameter source with an x-ray microanalysis instrument described elsewhere (S.A.Ditsman, V.G.Bogdanov, Izv.AN SSSR,Ser.fiz.27,427,1963). The intensity was found in fact to decrease rapidly as the source was moved away from the Rowland circle. The above conclusion, formulated and verified experimentally and theoretically for point sources, is applied without any convincing argument to extended sources, and it is concluded that placing an extended source close to the crystal, within the Rowland circle, will greatly reduce the luminosity of the spectrometer. The author has previously shown that a narrow but finite region exists within which a point source produces essentially the same luminosity as when it is in its proper position on the Rowland circle (Tr.In-ta metallurgii im.A.A.Baykova, No.11,24. Izd. AN-SSSR,M.1962). It is recommended that extended sources be located within this region. It is believed that the conclusions and recommendations of the present paper apply to spectrometers employing elastically deformed (bent) crystals, but that fur-

Card 2/3

TITLE: Mutual diffusion of components and the phase diagram of the system Ti-W

SOURCE: Soveshchaniye po metallokhimii, metallovedeniyu i primeneniyu titana i ego splavov, 6th. Novyye issledovaniya titanovykh splavov (New research on titanium alloys); trudy soveshchaniya. Moscow, Izd-vo Nauka, 1965, 43-47

TOPIC TAGS: titanium, tungsten, alloy phase diagram, metal diffusion

ABSTRACT: The mutual diffusion of titanium and tungsten was studied over the temperature interval of 1000--1600°C. The experimental procedure was described in an earlier publication by A. Ya. Shinyayev, V. V. Bondarev, and Ye. V. Sergeyeva (Sb. Metallovedeniye titana, Trudy 5-go soveshchaniya po titanu. Izd-vo Nauka, 1964, str. 289). The experimental results are presented graphically (see Fig. 1). It is concluded that the system Ti-W exhibits a two-phase region up to the melting point temperature of the alloys. From a perusal of literature data on the diffusion and solubility of other metals in titanium, it is concluded that tungsten belongs to that class of elements which exhibits only partial solubility in titanium.

"Therapeutic Effect of the Neuroleptics Fluphenazin (Lyogen) and Butyrylperazin (Randolectil)"

Sofia, Suvremenna Meditsina, Vol 17, No 1, 1966, pp 39-44.

Abstract: Results of treatment of psychoses with the phenothiazine derivatives Lyogen and Randolectil are reported. It was found that Lyogen had a slightly euphorizing effect. Randolectil was well tolerated by a patient who was allergic to a great number of psychopharmacological agents. In the authors' experience, if an obvious therapeutic effect was not produced by a neuroleptic drug after treatment for 30 days, further treatment with this drug served no useful purpose. A selective, individual response of patients to treatment with psychotropic drugs was observed, which did not depend on the nature of the disease, but solely on the chemical constitution of the drug. Russian and English summaries.

ABSTRACT: The problem of decomposition of a mixed-set distribution into normal distributions is considered. In some cases, this problem can be better solved on an analog computer. The authors' method permits first studying the effect of individual components on the general distribution; graphical techniques can be used only in the first approximation; thereupon, the results are systematically improved by the analog computer. Approximate formulas are derived for analog-computer processing the mixed sets. To determine the normal distribution by an analog computer, a differential equation is set up whose solution is a

TITLE: Tandem furnaces

SOURCE: Hutnik, no. 7, 1965, 268-272

TOPIC TAGS: metallurgic furnace, steel, pig iron

ABSTRACT: Production of steel in tandem furnaces is compared with other oxygen processes. The thermal balance in tandem furnaces is discussed. The output of these furnaces is very high, and it is possible to use pig iron of varying qualities. They operate economically from the point of view of utilities consumption; it is possible to use parts from Martin furnaces in the reconstruction programs involving tandem furnaces. Suitable methods of charging the furnaces are described; equipment manufactured by "Pohlig-Heckel-Bleichert" is recommended.

Abstract : Study of 12 infants every 2 weeks between 2nd and 24th week of life: eye and body movements, frequency and regularity of breathing from 7 pm to 6 am. Data indicate that gradual decrease in sleeping time and corresponding lengthening in time awake is all at the expense of the transitory states; deep-sleep time remains constant throughout period. Graph, 1 US reference.

TITLE: Sleep cycles in infancy [This paper was presented at the Third Interdisciplinary Conference on Experimental and Clinical Study of Higher Nervous Functions held in Marianske Lazne from 19 to 23 October 1964.]

SOURCE: Activitas nervosa superior, v. 7, no. 2, 1965, 143-144

TOPIC TAGS: psychology, man, human physiology

ABSTRACT: Three phases of sleep in infants are described. The waking, open eyes, irregular breathing, respiration rate 60/min. The transitory or light sleep, eyes alternately open and closed, respiratory rate 45/min. The deep sleep, eyes closed, respiratory rate 40/min, and after 24th week only 25/min. Phases of deep sleep appear repeatedly in about 50-60 min intervals. Total duration of light sleep decreases from a mean 82% in the 2nd week to 53% in the 24th. In the same period deep sleep increases from 15% to 37%. Orig. art. has: 1 figure. [JPRS]

Dittse, G.

TITLE:

Skylight polarization during twilight as an indicator of cosmic dust penetration (Summary)

SOURCE:

Akademiya nauk Kazakhskoy SSR. Astrofizicheskiy institut. Trudy, v. 3, 1962. Rasseyaniye i polarizatsiya sveta v zemnoy atmosfere; materialy Soveshchaniya po rasseyaniyu i polyarizatsii sveta v atmosfere. 236

TEXT:

The author deals first with the penetration of meteoric matter into the atmosphere, in particular of meteoric dust. The dust, which penetrates at high velocity, is slowed down and clusters initially at an altitude of 80 to 120km, and then sinks gradually lower down. Under the effect of the cosmic dust, the optical characteristics of the atmospheric layer corresponding to that altitude should differ from the optical characteristics of neighboring layers. The author suggests a method for ascertaining

Card 1/2

Skylight polarization ...

S/913/62/003/000/030/033
D405/D301

the presence of cosmic-dust clusters at these altitudes by measuring the polarization of light at the zenith during twilight. The paper gives the results of calculations of sky brightness and of the degree of polarization of skylight at the zenith for various models of the atmosphere, for a solar depression ranging from 1 to 15°. The following factors were taken into account in the calculations: refraction, solar and scattered light extinction in the atmosphere, in particular absorption by ozone, primary light scattering due to molecules and aerosols, and also dispersion. The first atmospheric model corresponded to average atmosphere-optical conditions. The other two models corresponded to an atmosphere containing high-altitude dust layers. These two models differed from each other by the size of the cosmic-dust particles. The theoretical calculations were compared with experimental polarization-measurements of skylight at the zenith.

Ditts, O. G.

Geodeziya (Geodesy) Moscow, Geodezizdat, 1957. 291 p. 20,000 copies printed.

Reviewers (mentioned in preface): Kolosov, B. A. and Danilevich, B.B., Docents.

PURPOSE: This is a textbook for students of construction and hydrotechnical engineering colleges.

COVERAGE: The book discusses the use of the All-Union coordinate grid, the interpretation of topographic maps, and methods of transit surveying, leveling, plane table surveying and tacheometric work. The last two parts deal with layout work and aerial photography and stereophotogrammetry. The following instruments are mentioned (usually accompanied by a photograph

TITLE: Biologically active DNA of bacteriophage

SOURCE: Zhurnal mikrobiologii, epidemiologii i immunobiologii, no. 9, 1965, 6-10

TOPIC TAGS: DNA, bacteriophage, serum, bacterial genetics

ABSTRACT: The author investigated the interaction between isolated double-stranded DNA of phage λ and spheroplasts to establish the basic biological properties of infectious DNA. Strains of Escherichia coli K 12 (λ) and an artificially lysogenized strain of E. coli C (λ) were used to obtain phage λ by ultraviolet induction. To identify the infectious agent with DNA of phage λ , its properties were compared with those of the intact phage. The author found that DNA isolated by phenol extraction from purified concentrated phage preparations is infectious for lysozyme spheroplasts but is not infectious for intact cells of penicillin protoplasts and spheroplasts obtained by freezing with subsequent thawing in the presence of lysozyme. DNA infectivity is destroyed by deoxyribonuclease but is not affected by ribonuclease, trypsin, antiphage serum, or heating at a temperature completely inactivating the intact phage. The optimal spheroplast concentration is $1-3 \times 10^8$ kg/ml. The EDTA concentration in the incubation mixture should not exceed 4-5 μ g/ml. The concentration

Borodin, V. A., and Il'yakin, Yu. F. On the stability of plane flows of a viscous fluid between two walls. Akad. Nauk SSSR, Prikl. Mat. Meh. 17, 569-578 (1953).
(Russian)

On doit à C. C. Lin [Quart. Appl. Math. 3, 111-142 (1945); ces Rev. 7, 225] l'étude de la stabilité de l'écoulement laminaire plan d'un liquide visqueux dans un canal à bords rectilignes et parallèles, animé de vitesses parallèles aux parois. Cet auteur ramène la question à la discussion d'une équation différentielle. Les auteurs effectuent cette discussion en utilisant la méthode bien connue de Galerkin dont la validité, en l'espèce, est justifiée en s'appuyant sur certains résultats de Keldysh. Les auteurs étudient alors, d'une manière approfondie, la stabilité des écoulements dont les profils des vitesses présentent des points d'inflexion; ceci paraît nouveau. Ils concluent à l'instabilité des régimes caractérisés par les profils des vitesses à inflexions disymétriques.

J. Kravchenko (Grenoble).

8 Dityakin, Yu. F. On stability and disintegration into drops
67 of a liquid jet of elliptic section. Izv. Akad. Nauk
SSSR, Otd. Tehn. Nauk 1954, no. 10, 124-130 (1954).
(Russian)

The jet, of ideal liquid surrounded by fluid, is disturbed in such a way that the surface varies periodically with time and with distance from the orifice. The author uses elliptic coordinates and Mathieu functions to find the critical frequency at which the jet becomes unstable. A dimensionless graph of frequency against pitch shows that the more nearly circular the section, the finer the drops.

L. M. Milne-Thomson (Greenwich).

TITLE: Influence of periodic oscillations of the speed and the density of the medium on the decomposition of a liquid stream (Vliyanie periodicheskikh kolebaniy skorosti i plotnosti sredy na raspad zhidkikh struy).

PERIODICAL: "Izv. Ak. Nauk, Otd. Tekh. Nauk" (Bulletin of the Ac. Sc., Technical Sciences Section), 1957, No.4, pp.115-120 (USSR).

ABSTRACT: In a number of practical cases involving the decomposition of a stream into drops, transition of a laminar flow into a turbulent one, etc., it is of considerable interest to study the influence of oscillations in the flow speed on the stability of the flow. It is also considered of interest to evaluate theoretically the influence of density oscillations of the gaseous medium surrounding the liquid stream on the decomposition of the stream. Such oscillations occur, for instance, in the combustion chambers of jet engines and may bring about a change of the conditions of the working process. The influence is theoretically investigated of the fluctuations in the speed and density of the medium surrounding the cylindrical liquid flow on the decomposition of the flow. The solution is effected by means of the method of small disturbances. It is shown that in the case of fluctuations in the speed of flow of a liquid and of the density of the medium the character and the width of the wave range of unstable

disturbances change and an infinite number of individual zones of unstable disturbances occur instead of the single zone which is characteristic in absence of fluctuations. The optimum wave length proved to be lower than that prevailing in absence of fluctuations, i.e. the fluctuations in the flow speed and density of the medium lead to a reduction of the dimensions of the drops produced during decomposition of the stream. The conclusions obtained from the theoretical analysis are qualitatively confirmed by the experimental results of Mieses, C. (Jet Propulsion, Vol. 25, No. 10, pp. 524-530, 534, 1955). The authors consider the stability of a circular cylindrical flow of a liquid and the coordinate system is so chosen that the stream is stationary and that the surrounding medium has a certain speed U . It is assumed that this speed and the density of the surrounding medium are periodic functions of time. The liquid is assumed as being ideal and the flow as being a purely potential flow. L.N.Britneva has assisted in the calculations. There are 3 graphs, 7 references, 6 of which are Russian.

TITLE: The use of Dimensionless Criteria to Generalise the
Results of Drop-size Measurements When Atomising
Liquids in Centrifugal Nozzles

PERIODICAL: Teploenergetika, 1959, Nr 11, pp 33-37 (USSR)

ABSTRACT: In recent years a good deal of work has been published on the relationship between drop-size, nozzle characteristics and operating conditions. However, the results do not seem to have been formed into any general system of dimensionless criteria, which would, however, be very useful. The dimensionless criteria that have been used to characterise the process of atomisation have either been based on the theory of a stable flow of liquid, or on dimensional theory. This article uses the dimensional theory to examine a centrifugal nozzle that creates a film of liquid of a certain thickness which breaks up into drops while moving in a gaseous medium. Then the relationship between drop size and film thickness is given by expression (1), which includes four criteria. The ✓

The use of Dimensionless Criteria to Generalise the Results of Drop-size Measurements When Atomising Liquids in Centrifugal Nozzles

first, called the Weber criterion, is the ratio of the inertia force to the surface tension force of the film. The second, called the Laplace criterion, is the ratio of the surface tension force to the viscosity force of the liquid. The third criterion is the ratio of the inertia force of the gaseous medium to that of the atomised liquid. The fourth criterion is the ratio of the viscosity forces of the gaseous medium and the atomised liquid. The reasons for choosing this particular system of criteria are explained. Treatment of previously published data by means of the new criteria is discussed. It is shown that the density of the medium enters into two of the criteria proposed. Consequently, in supplying the formula to a medium of lower density than the atmosphere it is necessary to know the influence of the density of the medium on the film thickness and the place at which it breaks up. As this relationship is unknown, the formula can only be used for atmospheric air density. The relationship
