TITLE: Electroanalytic method of studying the speed of oxygen consumption in  
tissues in vivo in a sanitary-toxicological experiment

SOURCE: Gigiyena i sanitariya, no. 9, 1966, 67-71

TOPIC TAGS: electroanalysis, oxygen consumption, rat, histology, toxicology

ABSTRACT:

The electroanalytic method of studying  $pO_2$  in the tissues of a living organism has been proven to be a sensitive test affiliated with the determination of the MPC (maximum permissible concentration) of a series of tissues. Experiments were conducted with white rats: in one group, a water solution of 2,4-dinitrophenol (DNPH) with a concentration of 1/2 LD<sub>50</sub> (1.5 mg/kg) was injected in the course of 80 days; in the second group the same dosage of DNPH was injected once; the third group was the control and received no injection. A specially constructed organic glass chamber which supplied 100% oxygen at a rate of 5 l/min, thus allowing a full exchange of the air with respired CO<sub>2</sub>, was used. An electronic self-recording potentiometer (YePP09) studied the oxygenic

ACC NR: AP6031639

condition in the tissues. The following coefficients were used to analyze the results:  $K_1$  represented the relationship of the maximal force of the current to the original force and also the degree of disturbance of the tissue after oxygenic stress.  $K_2$ ,  $K_3$ , and  $K_4$  represented the relation of the current forces at 60, 120, and 180 seconds after the first supply of oxygen. Analysis of the data showed that a single inoculation of DNPH produces a significant reduction in the saturation of oxygen in muscles, and increases oxygen consumption. In addition, a more severe experiment was conducted by applying arterial gaskets to the limbs and then inoculating DNPH. Analysis of this method also showed that a single inoculation of DNPH produces a significant increase (43%) in  $O_2$  consumption. It was concluded that the electroanalytic method permits correlation of respiratory intensity in intact muscles of living organisms and expression of respiratory kinetics by a constant of reaction speed. This method of registering  $O_2$  consumption in living tissues can also be used in tracing the effect of a small dose of DNPH over a long period of time. [WA-50; CBE No. 12]

ABSTRACT: A scientific methodical conference called by the Rizhskiy pedagogicheskiy institut (The Riga Pedagogical Institute) jointly with the Ministry of Education of the Latvian SSR debated measures to improve the polytechnical education of future teachers. The conference proposed replacing the state examination of teachers in special industrial disciplines, by the presentation of a diploma project on a given subject. The number of hours for teaching industrial drawing must therefore be increased.

TITLE: Is cavitation always harmful?

SOURCE: Tekhnika - molodezhi, no. 8, 1965, 5-6

TOPIC TAGS: cavitation, marine engineering, propeller blade

ABSTRACT: The principles of cavitation are discussed and its adverse effects cited. The development of cavitation during operation at high rates of speed is unavoidable and all measures to prevent it have been unsuccessful. Cavitation led to the discovery of supercavitation which, in turn, inspired the Russian scientist V.L.Pozdynin to design supercavitation propellers. The shape of the propeller blades causes rapid development of a cavity that closes behind the propeller, while the simultaneous decrease in resistance and lifting force make it possible to develop a sufficiently high efficiency. Supercavitation conditions set in at speeds of 10 to 100 m/sec or higher. Noise, vibration, and erosion at lower speeds can be eliminated by pumping air in the cavities. Thus, despite its

TITLE: Motion of a tilted disc under a free surface

SOURCE: Prikladnaya matematika i mehanika, v. 27, no. 4, 1963, 735-738

OPTIC TAGS: tilted disc, incompressible fluid, jet method, conformal mapping

ABSTRACT: The author considers the plane problem of determining the motion of a tilted disc under the surface of an ideal, weightless, incompressible fluid of infinite depth. The statement of the problem closely corresponds to the case of motion of a disc for large Froude numbers. For the solution he applies the methods of jet theory and the usual complex variable conformal maps. Orig. art. has: 24 formulas and 8 figures.

TITLE: On the minimum cavitation number and width of the cavity in plane and axisymmetric channels

SOURCE: AN SSSR. Izvestiya. Mekhanika zhidkosti i gaza, no. 5, 1966, 78-81

TOPIC TAGS: cavitation, fluid flow, cavity flow

ABSTRACT: The author studies the width of the cavity behind a body in plane and axisymmetric channels. Formulas are given for calculating the minimum cavitation number and also for finding the width of the cavity as a function of the cavitation number and the ratio of the transverse dimensions of the body in the channel. The results are given in the form of graphs and compared with data in the literature. Satisfactory agreement is observed in the region of maximum cross sectional areas of the cavity. The discrepancy increases with a reduction in the cross sectional area reaching approximately 12% when  $S=0$ , i. e. when the walls of the channel are removed to infinity. This contradiction is due to the differences in the computational schemes used. Curves are given showing the effect of the channel walls on the width of the cavity, with the ratio of the width in the channel to that in an unbounded

Card 1/2

ACC NR: AP6034542

fluid being laid off along the  $y$ -axis while the cavitation number is plotted along the  $x$ -axis. It is found that the width of the cavity increases as that of the channel is reduced for plane and circular channels with bodies of identical size and identical cavitation numbers. No matter how distant the walls, the area of the center section of the cavity behind a body in a channel is twice as great at the same minimum cavitation number as that of the center of the cavity behind a body in an unbounded fluid. This effect is briefly discussed and a physical explanation is given. Orig. art. has: 6 figures, 13 formulas.

Effect of age on gastric secretion. A. M. Vorob'ev  
and L. D. Brushtein. *Med. exp. (Ukraine)* 1936, No. 8,  
pp. 407-410. (1937) performed on 30 puppies (having  
Pavlov stomachs) for a period of 5 months beginning with  
the age of 3 months. As the puppies aged the same kind  
and quantity of food (milk, bread, meat) produced a  
greater quantity of gastric juice (per kg. of body weight),  
a greater percentage of solid residue, greater acidity and  
greater digestive power of the juice. In the younger pup-  
pies the period of secretion of gastric juice was short, the  
max. secretion occurring at the end of the first hr. With  
advancing age the increase in gastric secretion became more  
gradual, the max. secretion occurring during the third  
hr. in the oldest puppies. S. A. Corson

TITLE: Relationship Between Strength of Steel Mark 30KhG2S and  
the Temperature of Heating

PERIODICAL: Beton i zhelezobeton, 1960, Nr 1, p 35 (USSR)

ABSTRACT: Electro-thermic method of pretensioning of reinforced concrete constructions is widely used. In Tula Mechanical Institute tests were carried out to establish properties of strength of steel mark 30KhG2S subjected to heating and subsequent cooling. For this purpose 250 mm long samples were selected from reinforcing steel of standard profile mark 30KhG2S of 14 mm diameter. These were heated to 200, 300, 400, 500, 600 and 700°C and kept in the kiln for 30 minutes and then cooled down to the temperature of the air. The time of keeping the reinforcement under the increased temperature in the kiln secured constant properties of steel. Cooled-down samples were tested on tearing machine UIM-50. Illustrated graph shows that the obtained curve has maximum corresponding to temperature of 200°, which can be explained by the process of strengthening of the steel during its "ageing". After the increase of temperature above 200° the strength begins to fall. Temper-

Card 1/3

Relationship Between Strength of Steel Mark 30KhG2S and the Temperature of Heating

ature of 300 - 400°C does not cause decrease in the strength of samples in relationship to initial condition. The curve indicates rapid decrease in strength commencing at a temperature above 400°. At a temperature up to 500° the limit of strength is equal to 79 kg/mm<sup>2</sup>, up to 600° - 78 kg/mm<sup>2</sup>, and up to 700° - 68 kg/mm<sup>2</sup>. It follows that at a temperature of 600°C the point of yield of the steel is reached at a stress of 60 kg/mm<sup>2</sup>, that is the value of standard resistance for reinforcement from steel mark 30KhG2S. The point of yield of reinforcing steel when heated up to 700°C is 53 kg/mm<sup>2</sup>, which is lower than the standard resistance. Elastic properties of reinforcement became larger with increased temperature. In original condition the relative elongation was 60%, at 300° - 16%, at 500° - 18% and 600 - 700° - 20%. Properties of steel samples after heating in the kiln were also rechecked by heating using electrical current. Two 600 mm long samples were heated up to 500 - 600°C. After reaching 500°C the limit of strength was 80 kg/cm<sup>2</sup>, and after reaching 600° - limit of strength was 80 kg/mm<sup>2</sup>, which corresponds with the illustrated graph.

Card 2/3

69034

S/097/60/000/01/010/017

Relationship Between Strength of Steel Mark 30KhG2S and the  
Temperature of Heating

The obtained results show that reinforcement from steel  
mark 30KhG2S, with regard to its strength, could be heated  
up to the temperature of not more than 500°C, but the  
result is excessively high plasticity and it is therefore  
recommended not to use higher temperature of heating than  
300 - 350°C.

TITLE: On the problem of increased strength of hardened steel  
during tempering by passage of an electron current

PERIODICAL: Fizika metallov i metallovedeniye, v. 15, no. 5,  
467 - 470

TEXT: It has been established that steel tempered by the  
passage of electrical current has mechanical properties superior  
to those of steel tempered in a furnace. The cause of this  
difference has not yet been understood - hence the present investi-  
gation carried out on steels 5 and 35FC (35GS). The experiments  
(tensile tests, electrical-resistance measurements, determination  
of the temperature-dependence of internal friction) were conducted  
on wire specimens 14 mm in diameter, 450 mm long, quenched from  
860 °C, then tempered at various temperatures either in a furnace  
or by passage of an electric current. The results are reproduced  
graphically. In Fig. 1, the UTS ( $\sigma_u$ , kg/mm<sup>2</sup>), yield point  
( $\sigma_y$ , kg/mm<sup>2</sup>) and elongation ( $\delta$ , %) of steel 5 are plotted against

Card 1/4

E193/E385

On the problem of ....

the tempering temperature of specimens tempered in a furnace ( $\delta_5$  and  $\delta_{10}$  denote elongations measured on a gauge length of 5 and 10 mm, respectively). Similar curves reproduced in Fig. 2 have been constructed for steel 5 specimens, tempered by the passage of electric current. In Fig. 5, the decrease in electrical resistivity ( $\Delta\rho$ ,  $\Omega\text{mm}^2/\text{m}$ ) of steel 5 is plotted against the tempering temperature, curves 1 and 2 relating to specimen tempered, respectively, in the furnace and by electric current. Finally, the temperature-dependence of internal friction of steel 35GS, tempered at 250 °C in the furnace (curve 1) and by passage of electric current (curve 2) is demonstrated in Fig. 7. Conclusions - Improvement in the mechanical properties of steel tempered by passage of electric current can be explained in the following manner: electrical tempering brings about a greater decrease in the electrical resistivity of the steel, which indicates that carbon is more completely precipitated from the martensite, which means that a larger quantity of carbides is formed. In the same way, the increased width and height of the internal friction peaks in electrically tempered steel indicates a higher
