Vitamin A content in the blood of newborn children.
N. V. Fizhenko and M. P. Shcherbakova. *Voprosy
Pediat. i Okhrany Materinstva i Detstva* 16, No. 5, 29-31
(1948).—Vitamin A in a group of 50 babies (new born:
samples taken from the termination of placenta) varies
from traces to 24.4 γ %; carotene varies within similar
limits. Usually the figures are lowest in the 1st 6 months
of the year (av. 10.8 γ % vitamin A and 2.08 γ % caro-
tene), and highest in last 3 months (av. 12.82 γ %, and
14.80 γ % resp.). G. M. K.

Viscosity of industrial glasses. K. G. KUMANIN, V. V. FIZHENKO, AND B. I. ZHILINSKOM. *Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk, Inst. Mashinovedeniya, Soveshchanie Vyazkosti Zhidkostei i Kolloid. Rastvorov* (Conf. on Viscosity of Liquids and Colloidal Solns.), 1, 327-29 (1941); abstracted in *J. Soc. Glass Technol.*, 29 [133] 97 (1945).—At varying conditions of temperature, the inner structure of melts can be characterized by the viscosity and the coefficient of temperature. It is not possible to define exactly the upper and lower limits of the viscosity due to experimental difficulties. Attempts to classify experimental data are not successful owing to the insufficiency of comparison of isotherms (equal temperature) and isocoms (equal viscosity) and the great variety of industrial glasses. The temperature and the viscosity at the liquefying point, however, can represent a suitable criterion for comparison, thus giving a more exact picture of the change of viscosity in accordance with the chemical composition (isoliquids of the viscosity).

Dąbrowski Z., Flak S. Precasting of Concrete Girders Poststressed by Cables for the Warsaw Ice-Ring Grand Stand.

„Produkcja prefabrykowanych dźwigarów kablobetonowych do trybun sztucznego lodowiska w Warszawie". Inżynieria i Budownictwo. No. 1, 1955, pp. 13—16, 7 figs., 4 tabs.

The authors describe all the production phases of 52 precast concrete girders poststressed by cables. The span of the girders is 21 m. The cement brands and the quality of sand, gravel and steel used for the concrete are enumerated, and a description is included of the manner of preparing the reinforcements and moulding of the members, the batching and placing of the concrete, and the poststressing of the girders. The authors point out that not basalt grit but only granite should be used, since latter adheres better with the cement mix. They also find it advisable to use for the cable channels sheet metal tubes with walls 0.3—0.5 mm thick instead of gas pipes. Moreover the moulds may, without any deterioration in the surface finish of the precast units, be lined with black sheet instead of zinked sheet.

TITLE: Measurement of Capture Cross Sections of Electrons for Singly
             Charged and Doubly Charged Ions of Natural Gases (Izmereniye
             secheniy zakhvata elektronov odnozaryadnymi i dvukhzaryadnymi
             ionami v "sobstvennykh" gazakh)

PERIODICAL: Zhurnal Tekhnicheskoy Fiziki, 1958, Vol. 28, Nr 3, pp. 599-
             -611 (USSR)

ABSTRACT: Here the cross section for the capture of one and two electrons
             by means of doubly charged ions was measured and the dependence
             of these cross sections on the ion energy was determined. More-
             over the cross sections for the resonance capture of the elec-
             trons by means of singly charged ions were determined. All
             measurements referred to the cases of interaction of the ions
             of inert gases and of the atoms of natural gases. The cross
             sections in the case of the singly charged ions were measured
             in the ion energy-range of $3 \div 30$ keV and in the case of
             doubly charged ions in that of $6 \div 60$ keV. The here applied
             method for the determination of the cross sections is based on
Card 1/3   the recording of fast atoms or ions which had formed from the

Measurement of Capture Cross Sections of Electrons for Singly 57-28-3-24/33
Charged and Doubly Charged Ions of Natural Gases

ions of the primary beam due to collisions with the gas
atoms happening but once, which were accompanied by the
capture of the electrons. The cross sections σ_{10} of the re-
sonance capture of the electrons was measured by means of the
Ne^+-, Ar^+-, Kr^+- and Xe^+-ions. The obtained data agree with
theory by Firsov (reference 1). The cross sections σ_{21} of the
capture of one electron by means of Ne^{2+}-, Kr^{2+}-, Ar^{2+}- and
Xe^{2+}-ions were measured. In the energy range investigated the
cross sections σ_{21} continuously increase with the ion energy.
The existence of the capture process of two electrons by means
of Ne^{2+}-, Ar^{2+}-, Kr^{2+}- and Xe^{2+}-ions was experimentally observ-
ed. The cross section σ_{20} of the capture of two electrons de-
creases in all cases investigated with the increase of ion
energy. For this reason it was concluded that the capture of
two electrons is a resonance process. Doctor of Physical and
Mathematical Sciences N. V. Fedorenko advised the authors.
Head of the Laboratory Professor V. M. Dukel'skiy showed per-
manent interest in this work. There are 17 figures and 22
references, 11 of which are Soviet.

TITLE: The Determination of Capture Cross Sections of One and Two
            Electrons in Single Collisions of Double-Charged Ions With
            Gas Atoms (Opredeleniye secheniy zakhvata odnogo i dvukh
            elektronov pri odnokratnykh stolknoveniyakh dvukhzaryadnykh
            ionov s atomami gaza)

PERIODICAL: Zhurnal Tekhnicheskoy Fiziki, 1958, Vol. 28, Nr 3, pp.612-622
            (USSR)

ABSTRACT: The capture cross sections of one and two electrons in single
            collisions of double-charged Ne^{2+}-, Ar^{2+}-, Kr^{2+}- and Xe^{2+}-ions
            with the atoms of an inert "foreign" gas within the range
            of the ion-energy T from 6 to 60 keV are here determined in
            an experimental way. For the determination of the capture
            cross sections σ_{21} and σ_{20} the mass-spectrometry method
            of the recording of fast ions and fast neutral atoms (de-
            scribed in Reference 1) was employed. In the investigated
            energy range the authors observed an increase in the

Card 1/4

57-28-3-25/33

The Determination of Capture Cross Sections of One and Two Electrons in
Single Collisions of Double-Charged Ions With Gas Atoms

σ_{21}-cross sections with increasing ion-energy. When
$T = 60$ keV the σ_{21}-cross section is largest in the Xe^{2+}-
-Ar-pair ($\sigma_{21} = 2.10^{-15}$cm^2) and smallest in Xe^{2+}-He ($\sigma_{21} <$
$< 10^{-18}$cm^2). The existence of the capture process of two elec-
trons in the case of Ne^{2+}-ions in He, Ar, Kr, Xe, in the case
of Ar^{2+}-ions in Ne, Kr, Xe, in the case of Kr^{2+} in Ar, Xe
and in the case of Xe^{2+} in the Ar, Kr was determined in an
experimental way. In the case of the enumerated ion-atom-
-pairs the σ_{21}-cross section increases with increasing
ion-energy and is highly dependent on the nature of the
ion and of the atom. In all investigated pairs at the same
ion-velocity $\sigma_{21} > \sigma_{20}$, but in some pairs the cross sec-
tions σ_{21} and σ_{20} are very close to the absolute value.
E.g. at $T = 60$ keV for the Ar^{2+} - Kr-pair the cross section
$\sigma_{21} = 6.10^{-16}$ cm^2 and $\sigma_{20} = 5.10^{-16}$cm^2. As a rule σ_{21}
and σ_{20} are greater in collisions of light ions with heavy
atoms. In two endothermic cases the cross sections of the
capture of one electron and in 5 endothermic cases those of
the capture of two electrons were measured. In endothermic
cases the cross sections σ_{21} and σ_{20} as a rule decrease
with increasing absolute value of the "resonance-defect" ΔE.

Card 2/4

57-28-3-25/33

The Determination of Capture Cross Sections of One and Two Electrons in Single Collisions of Double-Charged Ions With Gas Atoms

In exothermic cases no definite dependence of the cross sections σ_{21} and σ_{20} on the quantity ΔE was found to exist. By comparing the data for "symmetrical" capture processes of two electrons differing by the sign of the quantity ΔE it was found that in case that $|\Delta E| > 10$ eV, σ_{20} in the exothermic case is considerably higher. In case that $|\Delta E| < 6$ eV the magnitude of the σ_{20}-cross section is little dependent on the sign of ΔE. The assumption is expressed that in the exothermic case, ΔE having a considerable value, an excitation of the colliding particles takes place. Data for the total capture cross section $\sigma_\Sigma = \sigma_{21} + \sigma_{20}$ are given. These characterize the general weakening of the double-charged ion-beams in the different gases.

The authors were advised by N. V. Fedorenko, Doctor of Physical-Mathematical Sciences and V. M. Dukel'skiy, Professor. There are 10 figures, 1 table, and 14 references, 4 of which are Soviet.

TITLE: Report on the Second All-Union Conference on Gas Electronics

ABSTRACT: The conference was organized by the Ac.Sc.USSR, the Ministry of Higher Education and Moscow State University. It was opened by the chairman of the organizing committee, M.A. Leontovich, Academician. During the plenary sessions of the conference, a number of survey papers were delivered. L.A. Artsimovich read a paper on "Production of Ultra-high temperatures in Plasma". A survey of the optical method of measurements was given in the papers by V.A. Fabrikant and S.E. Frish. S. Brown of the Massachusetts Institute of Technology gave a survey of the high-frequency methods of the investigation of stationary and non-stationary plasma (see p 1345 in this issue of the journal). N.V. Fedorenko read a paper entitled "Ionization and Inelastic Scattering During Atomic Collisions".

Card 1/15 L.A. Sena and Yu.M. Kagan deal with "Elementary Processes of Determining the Motion of Ions in Gas". A paper by Ye. Badareu (Rumania) dealt with "The Role of Resonance Recharging in the Kinetics of Ions". I.S. Stokol'nikov considered the initial stages of the development of sparks (corona-leader, main channel and the final channel). B.N. Klyarfeld gave a survey of the ignition processes of the discharge in highly rarified gases. The mechanism of the breakdown of a high-vacuum gap was elucidated in a paper by V.L. Granovskiy. L. Tonks (USA) expounded a theory of the motion of electrons in a magnetic trap (see p 1316 of this journal). Academician R. Rompe (Eastern Germany) described a number of experiments on non-stationary plasma conducted by himself. M. Steenbeck (Eastern Germany) gave a generalized theory of plasma. The conference was divided into six sections. The first section was presided over by L.A. Sena and was concerned with the elementary processes in gas discharge. The following papers were read in this section: I.A.M. Fogel'- "Transformation of Positive Ions into Negative Ones in Rarified Gases". Ya. M. Fogel' with V.A. Ankudinov and D.V. Pilipenko - Capture and Loss of Electrons During the Collision of Fast Atoms of Carbon and Hydrogen with the Molecules of Gases. M.Y. Fedorenko et al.- "Dissociation of Molecular Ions of Hydrogen During Collisions in Gas". N.V. Fedorenko and Ye.S. Solov'yev - "Capture   Cross-sections of Electrons in Multicharge Ions in Inert Gases". B.M. Kessen' et al.- "Experimental Investigation of the Resonance Recharging in Certain Single-atom Gases and Metal Vapours". O.B. Firsov - "Qualitative Investigation of Inelastic Collisions of Atoms". L.M. Volkova.- "Effective Excitation Cross-sections of the Spectral Lines of Potassium and Argon".

Card 3/15 I.P. Zapesochnyy and S.M. Kishko "Some Results of the Investigation of the Optical Functions of the Excitation Bands of a Negative System". A.A. Vorob'yev and A.G. Vlasov - "Investigation of the Scattering of the Electrons in a Betatron Chamber". The second section was presided over by B.N. Klyarfeld and was devoted to the problems of the electrical breakdown in rarified gases and in high vacuum. The following papers were read in this section: G.I.z. Maka-Linner and Yu.A. Matlitskiy.- "Electrostatic Control of the Ignition of Glow-discharge Tubes"(see p 1374 of the journal). S.V. Pshteyn et al. were concerned with the breakdown in a high-voltage mercury rectifier (see p 1378 of the journal). L.G. Guseva "Ignition of the Discharge in Non-uniform Fields at low Gas Pressures" (see p 1360 of the journal). A.S. Soboleva and B.N. Klyarfel'd - "The Discharge Phenomena Between a Point and a Plane at Gas Pressures of 10^{-3} - 1 mm Hg".

TITLE: Scattering of Multiple Charged Ions With Simultaneous
               Electron Capture

PERIODICAL: Zhurnal tekhnicheskoy fiziki, 1960, Vol 30, Nr 1,
               pp 49-56 (USSR)

ABSTRACT: Introduction: Except for the Ar^{2+} Ar^{+}, scattering of
               multiple charged ions with simultaneous partial or
               total neutralization has not yet been studied, and
               the authors undertook to measure the scattering of
               particles obtained from primary Kr^{+}, Kr^{2+}, Kr^{3+},
               and Ne^{2+} ions after their partial or total neutralization
               in neon or crypton. The authors investigated at the
               same time the small angle scattering of ions without
               change in charge which can differ from the elastic
               process by exciting or ionizing the atoms of the
               scatterer. (I) Methods of measurements: The apparatus
Card 1/10   consisted of a mass-monochromator producing a

Neutral particles reaching F_3, described in detail by
Flaks and Solov'yev (ZhTF,XXVIII, 599, 1958) were
registered by means of secondary emission. All
measurements were made for incoming ion energy of
33 kev. Keeping the pressure between 0.5 and $1 \cdot 10^{-4}$
mm Hg the authors maintained single collision conditions.
Incoming beam was of the order of 10^{-7} a, for singly
ionized atoms and 10^{-8} to 10^{-9} a, for the doubly and
triply ionized atoms. They measured differential cross
section not smaller than $1 \cdot 10^{-16}$ $cm^2 \cdot sterad^{-1}$ for
singly ionized atoms, $1 \cdot 10^{-15}$ $cm^2 \cdot sterad^{-1}$ for
doubly, and $1 \cdot 10^{-14}$ $cm^2 \cdot sterad^{-1}$ for triply charged
ions. Investigation in the 2.5 to 8° region showed
that in this interval the effects are below the
sensitivity of the apparatus. Probable error was between

Card 3/10

Scattering of Multiple Charged Ions With
Simultaneous Electron Capture

77329
SOV/57-30-1-8/18

+ 20 and 25%. (II) Results of measurements:
Figure 3 and 8 represent typical results. Overall
cross section was defined as

$$G(\theta) = \sum_{j=0}^{i}\left(\frac{\overline{d\sigma}}{d\omega}\right)_{if}.$$ (2)

The authors concluded that, (1) scattering with a
total neutralization of primary ions favors smaller
scattering angles while processes with partial neu-
tralization occupy a wider region; this is true in
the case of scattering on the same kind of gas or on
a "foreign" element. (2) The larger the number of
electrons captured during the full neutralization,
the wider the scattering angle distribution of particles
(see Fig. 8). (III) Evaluation of results: The
authors estimated the value of the total cross-section
using the equation

$$\bar{\sigma}_{if} = 2\pi \int_{0}^{\theta_{max}} \left(\frac{\overline{d\sigma}}{d\omega}\right)_{if} \sin\theta d\theta$$ (3)

Card 4/10   where θ_{max} fixed the angle beyond which the effects

were below the sensitivity of the apparatus. Compared
with results obtained by Flaks and others, who measured
the cross sections directly, the discrepancy was
never greater than 45%, which was within the limit of
errors of both sets of measurements. To estimate the
distance of approach, the authors used the classical
representation of trajectories, justified in view of
the small incident energies, and computed the sighting

parameter $\overline{\rho}$ (θ_o)

$$\rho(\theta_0) = \sqrt{2 \int_{\theta_-}^{\theta_{max}} \left[\sum_j \left(\frac{d\sigma}{d\omega} \right)_{ij} \right] \sin\theta \, d\theta} = \sqrt{2 \int_{\theta_0}^{\theta_{max}} G(\theta) \sin\theta \, d\theta}. \quad (6)$$

Table 2 contains computed values of $\overline{\rho}$ (θ_o) along with
with the values of θ_o for which the sighting parameter
is practically equal to the smallest internuclear

Card 7/10   distance r_{o} of the two colliding particles.

Scattering.of Multiple Charged Ions With ..   77329
Simultaneous Electron Capture   SOV/57-30-1-8/18

Table 2.

Pair	θ_o	$\rho(\theta_o)$, Å	$r_i + r_a$, Å
1	2	3	4
Kr$^+$ in Kr	1.5°	1	8
Kr^{2+} in Kr	0.7	1.5	7.5
Kr^{2+} in Ne	1.1	2.5	5.2
Ne^{2+} in Ne	0.9	7	3.5
Ne^{2+} in Kr	0.9	2	5.7
Kr^{3+} in Kr	0.75	2.3	6

The fourth row in Table 2 was computed using values
or formulas from the book by Gambosh (Statistical
Theory of Atom and Its Application, IL., M., 1951).
Whenever $\overline{\rho}(\theta_o)$ came out larger than $r_i + r_a$,
the authors deduced that Eq. (6) in that case is
not applicable. The differences. in. the width..of
the angular distribution in cases of partial and
total neutralization of incoming ions the authors
tried to explain in the following manner: At an
Card 8/10   approach, the potential function of the ion and atom

Scattering of Multiple Charged Ions With   77329
Simultaneous Electron Capture   SOV/57-30-1-8/18

looks like V(r) curve 1 in Fig. 9.

Fig. 9.
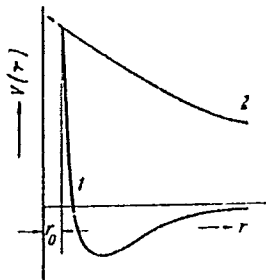

If there is no change in ionization or if there

is a total neutralization, the V(r) curve remains
the same. In the case of a partial neutralization,
however, the interaction after collision is given
by the Coulomb curve 2. Professors V. M. Dukel'skiy
and D. M. Kaminker discussed the results, and A. M.
Shchenkov helped in the adjustment of the experi-
mental devices. There are 9 figures; 2 tables; and

TITLE: Ionization of Inert Gases by Multiply Charged Ions

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960,
             Vol. 38, No. 3, pp. 719-725

TEXT: Shervin (Ref. 2) investigated the ionization of hydrogen- and helium
molecules by multiply charged ions and found the ionization cross section to
be proportional to the square of the primary ion charge. This is in agreement
with the theory of collision ionization at high energies, but not with the
latest concepts of the mechanism of ionization. With a view to clarifying this
point, the authors of the present paper measured the ionization cross sections
for single collisions of the ions Ne^+, Ne^{2+}, Ne^{3+}, Kr^+, Kr^{2+}, Kr^{3+}, Xe^+,
Xe^{2+}, Xe^{3+}, and Xe^{4+} with the atoms of the gases Ne, Kr, and Xe. The experi-
mental setup had already been described in previous papers (Refs. 4-6). The
measuring condenser employed here is closely described, and is schematically
shown in Fig. 1. Measurements were made at a gas pressure of 1.10^{-4} torr,

Card 1/3

B006/B014

which in turn was measured by means of an ionization gauge. Saturation
currents, I_+ and I_- were measured on the plates of the measuring condenser
in order to determine the cross sections. Formula (1) $\sigma_- = zI_-/NlI_0$;
$\sigma_+ = zI_+/NlI_0$ can then be used to determine the total cross section of the
liberation of electrons (σ_-) and the total cross section of the formation
of secondary ions (σ_+); I_0 is the primary current of the beam, z is the
multiplicity of the charge of primary ions, N the number of atoms per cm^3 of
gas, l is the length of the measuring electrodes. σ_- is interpreted as being
the total ionization cross section. It further holds that $\sigma_+ - \sigma_- = \sigma_0 - \sigma_1$,
where σ_0 is the "total cross section" for capture, σ_1 the "total cross section"
for stripping. In the energy range under investigation, $\sigma_1 \ll \sigma_0$, it holds
that $\sigma_+ - \sigma_- \approx \sigma_0$. The relative error obtained when measuring σ_- and σ_+ is
estimated as being 20%. Fig. 3 shows the dependence of the total ionization
cross sections σ_- as a function of the kinetic energy of primary ions in
six diagrams. Figs. 4 and 5 show the same functions for the capture cross

                                                                     B006/B014

sections: Fig. 4 offers a comparison between the values obtained by the poten-
tial method $(\sigma_+ - \sigma_-)$ and by the method of recording fast atoms. Fig. 5 of-
fers a comparison of the potential method with the mass-spectrometric method.
Results obtained did not confirm the quadratic law found by Shervin; the di-
verging results by Shervin are explained by the fact that Shervin did not
measure the cross sections at one and the same kinetic energy of the ions.
Results given here (voltage range 3-30 kev) indicate that the ionization cross
section for equal ion energies is practically independent of the charge of the
primary ion. For all ion-atom pairs a continuous growth of the cross section
with increasing kinetic energy of the primary ion was observed. Moreover, it
was found that results of measurement are in general well described by the
formula (equations (5) and (7)) given by O. B. Firsov (Ref. 1). This is
illustrated in Fig. 6. The authors finally thank Professor V. M. Dukel'skiy
for a discussion, and A. M. Shchenkov for his practical assistance. There are
6 figures and 11 references, 8 of which are Soviet.

AUTHOR: Flaks, I. P.

TITLE: Ionization in collision of singly charged ions and of Ne
            and Kr atoms with atoms of noble gases

PERIODICAL: Zhurnal tekhnicheskoy fiziki, v. 31, no. 3, 1961, 367-375

TEXT: The present paper is a report on the measurement of the total
production cross sections σ_- of free electrons and σ_+ of slow secondary
ions in plain collisions of Ne^+ and Kr^+ ions and of fast Ne^o and Kr^o atoms
with atoms of all noble gases in the energy range of 3 - 30 kev. In these
measurements, the author employed the capacitor method. Reference is
made to a synoptic article by N. V. Fedorenko (UFN, 58, 481, 1959). The
present paper is a continuation of a paper by N. V. Fedorenko, I. P. Flaks,
L. G. Filipenko (ZhETF, 38, 719, 1960) and is intended to give further
explanations concerning the effect of the charge of the primary particle
upon the total ionization cross section of the gas atoms by comparing the
data on the cross sections of singly charged ions with those of fast

Card 1/11

20931

Ionization in collision....

S/057/61/031/003/016/019
B125/B209

neutral atoms. The author used the data on the cross sections σ_- and σ_+ also for determining the total stripping cross section of fast atoms, and in the case of some ion-atom pairs also for determining the total capture cross section of electrons through ions. Moreover, the author repeated the measurements of the total cross sections for $Ne^+ + Ne$, $Na^+ - Kr$, $Kr^+ - Kr$, and $Kr - Ne$ pairs, which have been made in the above paper. The experimental apparatus has already been described in the above-mentioned previous paper, as well as in papers by I. P. Flaks, Ye. S. Solov'yev (ZhTF, 28, 599, 612, 1958) and I. P. Flaks, L. G. Filipenko (ZhFT, 29, 1100, 1959). The slit system 16, 18, 19, and 20 (Fig. 1) guaranteed a proper collimation of the beam. The pressure in the collision chamber was measured by an LM2 ionization pressure gauge. The cross sections σ_- and σ_+ were calculated from the approximation formula for single collisions:

$$\sigma = \frac{kT_0}{pl}\left[\left(\frac{N}{N_0}\right)_p - \left(\frac{N}{N_0}\right)_\phi\right]$$

(1). In this formula, N_0 denotes the intensity of the primary beam of ions or fast neutral atoms, N - the intensity of the electron or ion saturation current impinging

Card 2/11

20931

Ionization in collision...

S/057/61/031/003/016/019
B125/B209

upon the measuring strip, 1 the length of these strips, T_0 and p the temperature and pressure of the gas in the collision chamber, and k Boltzmann's constant. The index p indicates current measurements in the gas to be examined, and the index ϕ indicates current measurements in the residual gas. The relative probable error in the determination of the error was below 15%. The second section of the paper is devoted to the results of the measurements: A. Total ionization cross section: Fig. 2 illustrates the total ionization cross sections in collisions of Ne^+ and Kr^+ ions as well as of fast Ne^0 and Kr^0 atoms with He, Ne, Ar, Kr, and Xe atoms as depending on the kinetic energy of the impinging particles. The ion charge affects the absolute value of σ_- only slightly. B. Total production cross section of secondary ions: Fig. 3 presents the energy dependence of the total production cross section $\sigma_+(T)$ of ions and fast Ne and Kr atoms in collisions with the atoms of all noble gases. The relation $\sigma_- = 2\sigma_+$ is valid with fairly good accuracy. Figs. 3, 4, and 5

Card 3/ 11

Ionization in collision...

20931

S/057/61/031/003/016/019
B125/B209

depict the total electron capture cross section and the total stripping cross section of neutral atoms: The difference between the measurements of the present paper and those made by F.J.De Heer, W. Huizenda, and J. Kistemaker (Physica, 23, 181, 1957) is not greater than 30%. Discussion of results: According to calculations made by O. B. Firsov (ZhETF, 39, 1517, 1959), the universal curve established by Firsov agrees with the experiment for collisions of gas atoms with ions of various charges. The conclusions drawn from data of a paper by Fedorenko, Flaks, Filipenko (viz., that the total ionization cross section depends only slightly on the charge of the primary particle) hold also for the ionization of gas atoms by fast neutral atoms. This is also illustrated by Fig. 6. The relatively small differences in the cross sections σ (Figs. 6, 2) are evidently due to the individual characteristics of the colliding particles. In the collision of two atomic particles, the escape of weakly bound electrons is the most probable, independently of the atomic particle in whose shells they are located. In the collision of a light primary particle with a heavy atom, ionization of the atom is more likely to occur, whereas in the collision of a heavy primary particle with a lighter atom, stripping is the more probable reaction. The increase in the ionization or stripping cross section in a gas is probably due to

Card 4/11

S/057/61/031/003/016/019
B125/B209

particular quantum-mechanical effects. The curve for $\sigma_-(v)$ for an Ar^0-Ar pair runs between the $\sigma_-(v)$ curves of Ne^0-Ne and Kr^0-Kr pairs, which were determined by the author. The author thanks Professor N. V. Fedorenko and V. M. Dukel'skiy for their interest in the present paper and for valuable hints. G. N. Ogurtsov and A. M. Shchenkov assisted in the experimental part. TITLE: Production of slow ions in gases by fast atom and ion beams

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 41,
             no. 4(10), 1961, 1094-1103

TEXT: The authors determined the production cross section σ_{0k} of slow ions
with the charge k in order to explain its dependence on the charge of the
primary particles. Collisions between Ne, Ar, Kr, and Xe atoms and fast
Ne^{0}, Ne^{+}, Ne^{2+}, and Ne^{3+} particles, as well as between Kr and Xe atoms and
fast Kr^{0}, Kr^{+}, Kr^{2+}, and Kr^{3+} particles have been studied. The experimental
arrangement which has been described previously (I. P. Flaks. ZhTF, 31,
367, 1961), was supplemented by an analyzer for slow secondary ions (Fig.
1). Measurements were made with primary particle energies of 3 - 30 kev.
The ion production cross section was determined from the relative line
intensity. In general, the overall error did not exceed 15%. It was

Card 1/5

28924

Production of slqw ions in gases by ...   B108/B102

found that, as a rule, $\mathcal{6}_{0k}$ increases with the charge and the energy of the primary particles. In atom-atom collisions, only pure ionization is responsible for the production of slow ions. With rising charge of the primary particles, ionization is more and more governed by the contribution of resonance charge exchange and of ionization with capture. The last item is evaluated for collisions between atoms and singly-charged ions. Professor V. M. Dukel'skiy is thanked for a discussion. There are 8 figures, 1 table, and 9 Soviet references.

AUTHORS: Flaks, I. P., Ogurtsov, G. N., Fedorenko, N. V.

TITLE: Ionization by collision between Ne^{n+} and Xe and between Xe^{n+} and Ne atoms (n = 0, 1, 2, 3, 4)

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 41, no. 5(11), 1961, 1438 - 1442

TEXT: In order to clarify the effect of the charge of ionized atoms upon the production of free electrons, the authors measured the total ionization cross section σ_- (accuracy 15%) for single collisions between fast charged and neutral atoms. A method described by N. V. Fedorenko, I. P. Flaks, and L. G. Filippenko (ZhETF, 38, 719, 1960) has been used. The accelerating voltage ranged from 3 to 30 kv. Results of the measurements: The total ionization cross section σ_- of Xe atoms as a function of the Ne^{n+} velocity v is shown in Fig. 1. Fig. 2 renders σ_- of Ne atoms as a function of the Xe^{n+} velocity v. It was found that σ_- increased for

Ne^{n+} - Xe and decreased for Xe^{n+} - Ne with increasing fast-particle charge n. The results are interpreted as follows: The increase of σ_- with rising charge of the fast particles is due to the possible exothermic ionization processes involving capture. In Ne^{n+} - Xe collisions, the ionization process of Xe predominates over the stripping process of Ne^{n+} which requires a considerably higher energy. The stripping process can add to a decent contribution only in Ne^0 - Xe collisions. The dependence is the opposite when ionization with capture is an endothermal process and when the main contribution to σ_- is due to stripping of fast atomic particles. Professor V. M. Dukel'skiy is thanked for discussions. O. B. Firsov (ZhETF, <u>36</u>, 1517, 1959) is mentioned. There are 2 figures and 8 Soviet references.

TITLE: Charge exchange of Xe^{3+} and Xe^{4+} ions in neon

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 42, no. 3, 1962, 721 - 724

TEXT: The capture cross section of one electron in single collisions of fast Xe^{3+} and Xe^{4+} ions with Ne atoms was measured with an experimental arrangement as described in previous papers (ZhTF, 28, 599, 612, 1958; ZhTF, 29, 1100, 1959). For accelerating voltages between 2 and 30 kev, the total capture cross sections σ^{32} and σ^{43} attain values up to $10^{-15} cm^2$. σ^{32} is larger than σ^{43} and attains a maximum value at a relative ion velocity of $v \approx 1 \cdot 10^7$ cm/sec. σ^{43} increases with increasing energy of the Xe^{4+} ions in the entire velocity range investigated. A comparison of the experimental data with results calculated by the Landau-Zener method of pseudo-intersection of potential energy curves (formula

$$\sigma^{nm} = (kT_0/pl)\,[(N_m/N_n)_p - (N_m/N_n)_\phi],   (3))$$

Card 1/2

Charge exchange of Xe^{3+} and...

TITLE: Charge exchange and ionization during collisions of nitrogen atoms and
ions with hydrogen molecules

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 33, no. 6, 1963, 748-753

TOPIC TAGS: charge exchange, ionization cross section

ABSTRACT: Charge exchange and ionization processes during collisions of atomic
particles N sup 0, N sup +, N sup 2+, and N sup 3+ with H sub 2 molecules have
been investigated and their collision cross sections measured within the range
of accelerating voltages from 1 to 30 kv. The investigation included the
measurement of charge-exchange cross sections when the ionic charge is totally
or partially neutralized and measurements of total-ionization cross sections for
the pairs N sup 0--H sub 2, N sup +--H sub 2, N sup 2+--H sub 2, N sup 3+--H
sub 2, and N sup 0--H sub 2. The experimental apparatus consisted of an arc-
type ion source operating in a longitudinal magnetic field, a magnetic

Card 1/2

2

monochromator for isolating the primary-ion beam of a given charge, a collision chamber with a sectionalized condenser for extracting free electrons and slow ions produced in gas, a magnetic analyzer for isolating fast ions subjected to partial neutralization, and a charge-exchange chamber for obtaining a beam of neutral atoms. It was found that in the range of average energies the curves of single-electron transfers have a flat maximum, while for N sup $3+$ the Sigma sup 32 curve increases continuously. The cross sections of single-electron transfers are virtually independent of nitrogen-ion charge and reach a magnitude of $(6-7) \times 10$ sup -16 cm sup 2. The cross sections of double-electron transfers do not exceed 1.5×10 sup -16 cm sup 2. The total cross section of ionization is approximately equal for the pairs N sup $+$—H sub 2 and N sup $2+$—H sub 2 and increases sharply for N sup $3+$ ions. "In conclusion the authors express deep gratitude to N. V. Fedorenko for his valuable recommendations and constant interest in this work." Orig. art. has: 5 figures and 1 formula.

TITLE: Ionization produced during collisions of alkali metal atoms with gas mole-
cules

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 2, 1965,
379-385

TOPIC TAGS: collision, collision cross section, gas ionization, alkali metal, atom

ABSTRACT: The results are presented of extensive investigations of ionizing colli-
sions between Li, Na, K, and Cs fast atoms and He, Ne, Ar, Kr, and Xe atoms and H_2
and N_2 molecules. The study was performed in the 3—30 kev energy range. The
average results of independent measurements are presented in a table which gives
the cross sections of free electron production and of ionization and stripping
cross sections. When possible, the data obtained were compared with those of other
authors. A comparison of ionization cross sections of gases with stripping cross
sections of alkali metal atoms showed in many cases the prevalence of ionization
events. It is stressed, however, that in the interactions of alkali metal molecules
with the molecules of H_2 and N_2, the stripping cross sections prevailed over the
ionization cross sections of the molecules in the whole range of energies. This
Card 1/2

L 01217-66

ACCESSION NR: AP5021095   3

difference was most marked in Li-H_2 and Na-H_2 collisions, i.e., in the collisions
of the lightest particles. As a rule, the ionization cross sections showed a con-
tinuous increase with the increasing velocity of the colliding particles. At a
given velocity, the cross sections increased with the increasing atomic numbers
of the particles. Here, however, an exception was observed for pairs with close
values of their atomic numbers (e.g., Li-He, Na-Ne, K-Ar, Cs-Xe). The authors
feel that their work may be useful in the corpuscular diagnosis of plasmas, and in
the study of ionic engines, astrophysics, and mass-spectrometry. Orig. art. has:

TITLE: Ionization of gases by alkali metal ions

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 35, no. 11, 1965, 2076-2082

TOPIC TAGS: inert gas, alkali metal, positive ion, ionization cross section, nitrogen, hydrogen, gas ionization

ABSTRACT: The cross sections for ionization of H_2 and N_2 molecules and He, Ne, Ar, Kr, and Xe atoms by 1-30 keV Li^+, Na^+, K^+, and Cs^+ ions were measured with apparatus and techniques that have been described elsewhere (I.P.Flaks, ZhTF, 31, 367, 1961; B.I.Kikanin, G.N.Ogurtov, N.V.Fedorenko, and I.P.Flaks, ZhTF 49, 379, 1965), and the results are presented graphically, discussed, and compared with the results of other investigators and with the theory of O.B. Firsov (ZhETF, 36, 1517, 1959). The beam current was 10^{-7}-10^{-8} A; the pressure in the collision chamber was kept below 1.5 x 10^{-4} mm Hg in order to minimize multiple collisions; the ionization cross sections were derived from measurements of the electron currents. The results were found to be in good agreement with those of W.Sherwin (Phys.Rev., 57, 814, 1940) and J. van Eck, F.J. de Heer, and J. Kistemaker (Proc. V Int. Conf. on Ioniz. Phenom. in Gases, 54,

Card   1/3   UDC: 537.56

L 10672-66

ACC NR: AP5028324   ⊘

Munich, 1964). Larger cross sections were found by C.A.Frische (Phys.Rev., 43, 160, 1933) and N.V.Fedorenko (ZhTF 31, 367, 1961). The discrepancy between the present Na^+ --Ar cross sections and those of Fedorenko are ascribed to incorrect pressure measurements by Fedorenko. The interactions of Ar and Kr with Na^+, K^+, and Cs^+, of Ne with Na^+ and K^+, and Xe with K^+ and Cs^+ satisfied the conditions for the applicability of Firsov's statistical theory (loc. cit.). The measured ionization cross sections lay close to Firsov's universal curve, and it is concluded that Firsov's approximate theory affords a useful description of the magnitudes and energy dependences of the cross sections for ionization of inert gases by alkali metal ions. All the cross sections increased monotonically with increasing energy of the bombarding ion. With the two exceptions noted below, the cross section for ionization of an inert gas atom by an alkali metal ion was very nearly equal to the cross section for ionization of the same inert gas atom by the corresponding neutral alkali metal atom. The two exceptions found to this rule are: 1) The measured cross sections for ionization by Cs^+ ions were considerably greater than the corresponding cross sections for ionization by Cs atoms. This is ascribed to appreciable contribution of electron stripping from the Cs^+ ion to the measured cross sections for ionization by Cs^+ ions. (The cross sections for ionization by Cs atoms were measured by a different technique (Flaks (1961), loc. cit.) and electron stripping from the Cs atoms did not contribute to the observed cross sections.) 2) Except for ionization of He by Li^+, the cross

sections for ionization of inert gases by alkali metal ions having the same electron

Card 2/3

L: 10672-66

TITLE: Dissociative charge exchange and ionization in collisions of neon atoms and ions with carbon monoxide

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 36, no. 1, 1966, 117-122

TOPIC TAGS: ionization cross section, carbon monoxide, neon, charge exchange, excitation energy, positive ion, particle collision

ABSTRACT: The authors have measured the cross sections for production of C^+, O^+, O^{2+}, O^{2+}, C^{3+}, CO^+, CO^-, C^-, and O^- ions in collisions between CO molecules and Ne atoms and Ne^+, Ne^{2+}, and Ne^{3+} ions accelerated in potentials from 3 to 30 kV. The experimental apparatus and technique have been described in a series of earlier papers by the authors and collaborators (ZhETF, 41, 1438, 1961; ZhETF, 38, 719, 1960; ZhTF, 31, 367, 1961; ZhETF, 41, 1094, 1961). The cross sections for production of positive ions were measured with an accuracy of 15%; the cross sections for production of negative ions were measured with less accuracy. The results are presented graphically and are discussed. The total ionization cross section increased monotonically with incident

Card 1/2   UDC: 537.56

L 21709-66

ACC NR: AP6004886   /

particle velocity; total ionization cross sections as large as 8×10^{-16} cm^2 were measured. The total ionization cross section was nearly independent of the charge on the incident particle; from this it is concluded that "potential ionization" processes are not significant. The cross sections for production of the various positive ions are discussed in terms of possible endothermic and exothermic reactions, and it is concluded that processes leading to the excitation of reaction products are more probable than the "potential ionization" processes previously detected by the authors and N.V.Fedorenko (ZhETF, 41, 1438, 1961) in collisions between multiply charged ions and rare gas atoms. Cross sections for production of O^-, C^-, and CO^- ions were of the order of 10^{-18}, 10^{-19}, and 10^{-20} cm^2, respectively. The detection of CO^- ions with lifetimes exceeding 10^{-6} sec is significant, because the possibility of the existence of a stable CO^- ion has been disputed (D.V.Pilipenko and Ya.M.Fogel', ZhETF, 42, 936, 1962). The authors thank N.V.Fedorenko for valuable discussions and advice, and his interest in the work. Orig. art. has: 27 (chemical) formulas and 8 figures.

ORG: Physicotechnical Institute im. A.F.Ioffe, AN SSSR, Leningrad (Fiziko-tekh-nicheskiy institut AN SSSR)

TITLE: Charge exchange of alkali metal ions in collisions with gas atoms and molecules

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 36, no. 3, 1966, 491-496

TOPIC TAGS: charge exchange, particle cross section, alkali metal, neon, argon, krypton, xenon, nitrogen, hydrogen, collision cross section

ABSTRACT: The charge exchange cross sections of 1 to 30 keV Li^+, Na^+, K^+, and Cs^+ ions on Ne, Ar, Kr, and Xe atoms and H_2 and N_2 molecules have been measured by a single collision technique. The authors have described their apparatus in detail elsewhere (ZhETF, 49, 379, 1965; ZhTF, 35, 2076, 1965; ZhTF, 29, 1100, 1959). The ion beam passed through the collision chamber containing the target gas at a pressure of about 1.5×10^{-4} Hg and was swept clear of charged particles by an electrostatic field. The neutral particles remaining in the beam were received in a Faraday cup and their flux was determined from the secondary electron emission to which they gave rise. A background flux measured with the collision chamber empty was subtracted from the measured flux before the cross section was computed. The geometry was such

Card   1/2

L 25499-66

ACC NR: AP6011395 2

that particles scattered through angles less than 5° would be recorded. It is esti-
mated that at energies below 3 keV, loss of particles from the beam by scattering may
have resulted in underestimation of the cross section by as much as 20%. All the
measured charge exchange cross sections increased with increasing relative velocity
of the colliding particles, as would be expected on the basis of the adiabatic hypo-
thesis in view of the large energy defects. The cross sections at 30 keV ranged from
10^{-17} to 3×10^{-16} cm^2. The cross sections of the different alkali metal ions on
the same target gas and for the same relative velocity increased with increasing mass
of the ion, even though the energy defects are greater for the heavier ions. This
phenomenon is explained as a result of the greater polarizability of the heavier
alkali metal atoms. The present results are in good agreement with those of N.V.
Fedorenko (ZhTF, 24, 2113, 1954) for Na^+ on Ar and with those of S.K.Allison,J.Cuevas,
and M.Garcia-Munoz (Phys.Rev.,120, 1266, 1960) for Li^+ on N_2 but there are large
discrepancies between the present results and other data in the literature. The
authors thank N.V.Fedorenko for his interest and valuable advice, and G.V.Dubrovskiy
for discussing the results. Orig. art. has: 3 formulas, 6 figures and 1 table.

TITLE: A means of erecting railroad bridges of arched-span construction from separate sections. Class 19, No. 178393

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 3, 1966, 28

TOPIC TAGS: bridge, bridge construction, structural engineering, railroad bridge, cantilever bridge

ABSTRACT: This Author Certificate presents a means for erecting railroad bridges of arched span construction from separate sections. The sections are suspended and joined with struts of the structure above the arch by temporary sloping and horizontal members. These members serve as cross-stays and upper booms. The sections also feature a cantilever truss (see Fig. 1) with a triangular framing, the lower girder of which forms a semi-arch. The upper girder of the cantilever truss is set above the travel span, which includes separate elements of the truss used in mounting and elevating the structure. These members subsequently form a triangular cantilever

11 - joints.

frame, cross-stays and semi-arch sections. Each panel thus formed serves as a
support for the next panel. The panels are rigidly fastened along the entire face,
the process being repeated until the entire semi-arch is formed. Then cables are
placed between the link sections and the support. When the cables are tightened,
the semi-arches are rotated with respect to the support section, thus unloading
the diagonal and horizontal members of the cantilever. The cables are removed, after
which the travel-span plates are placed upon the structure above the arch between
the link sections of the semi-arch and the support. When the wearing surface is
completely laid, the remaining part of the cables is tightened. Favorable working
conditions for the support are created by freeing the support from one-sided loadings;
assembly of the semi-arch takes place simultaneously on both sides of the pier, with
each addition being a cantilever addition. The abutment portion of the semi-arch is
prepared in place between the first support block of the semi-arch and the pier.
Forces in members of the cantilever are lessened by the introduction of stiffener
cables in the upper girder at 1/2--2/3 of its design length. Moments in panels on
the semi-arch are reduced through a skewed arrangement of axes of diagonals relative
to points of intersection of the axes of vertical members and the semi-arch blocks.
Joints are placed between adjacent semi-arches on the assembled panels, thus
controlling the position of cantilever frames in the span. Orig. art. has: 1 figure.

TITLE: Trial application of radiometric investigations for direct oil-field searches in Bashkiriya

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 11, 1962, 59-60, abstract 11A357 (In collection: Yadern. geofiz. pri poiskakh polezn. iskopayemykh, M., Gostoptekhizdat, 1960, 206-219)

TEXT: The institut GiRGI AN SSSR (Institute GiRGI, AS USSR) and the Trest Bashneftegeofizika (Bashkir Petroleum Geophysics Trust) conducted joint investigations on the territory of the Bashkir ASSR in order to clarify the potentialities of radiometric methods in searches for oil and gas fields. Areal airborne gamma-ray surveying was carried out in areas with an unestablished oil content and also over known oil fields, on a scale of 1:100,000. This was followed by ground operation detailing: car and foot beta-gamma-ray surveying, mapping drilling, and soil-lithologic mapping with the

Card 1/3

Trial application ...

selection of samples for laboratory research. The following complex of laboratory investigations was employed to analyze the rock and soil samples: 1) radiometric determination, 2) pH and humus determinations, 3) mechanical analysis, and 4) spectral analysis. It is mentioned that the zone, in which the gamma-activity of surface deposits inside the boundary of a pool is characteristically lowered and reaches 20-25% of the surrounding field's intensity, is outlined by a band of heightened gamma-field intensity values. These exceed the background values outside the anomaly by up to 10%. Thus, the overall effect of an anomaly increases up to 35% from the average background. However, variations in the intensity of the gamma-field, which are connected with the influence of different surface factors (lithology of the covering and indigenous deposits, topography, drainage, soil and plant cover), reach 35-50% of the measurable value and are a serious impediment. Therefore allowance was made in the interpretation for the effect of these factors on the radiometric field by comparing radiometric, geologic, topographic and structural maps in order to eliminate anomalies related to their influence. More than 70 zones of reduced gamma-activity, of which

48 were subjected to further study, were revealed as a result of the
work.   It is concluded: 1) the distribution of anomalies over oil
fields and in areas with an unestablished oil content is close, which
confirms the similarity of the genesis of these anomalies; 2) of the
total number of anomalies obtained over oil fields 89% pertains to
anomalies, which cannot stem from the influence of surface factors
or can be explained only partially. This circumstance indicates
that effective interpretation of gamma-ray surveying data may be car-
ried out subject to allowance being made for the influence of surface
factors. Oil fields were revealed by subsequent drilling on several
of the radiometric anomalies detected. On the basis of the results
obtained it is concluded that the radiometric method of seeking oil
fields is effective geologically, and it is recommended that the'
method should be included in the complex of geophysical investiga-
tions.
