Reevaluation of the Somogyi method for determination of
Sugars in Urine. J. Clin. Pathol. 1962; 15: 270-273.

The Somogyi method for sugar estimation in urine is based on the reduction of ferric ions by glucose. The reaction is catalyzed by insulin. The color produced is measured at 500 m μ . The method is subject to interference by many substances. The present method is based on the reduction of ferric ions by glucose in the presence of insulin and ferric citrate. The color is measured at 540 m μ . The method is more specific and less subject to interference than the Somogyi method. As compared with the Somogyi method, the new method is more sensitive and more rapid. It can be used to determine glucose in urine with excess HNO₃. It can also be used to determine glucose in blood. The proposed analysis takes 40 min. and requires no reduction of 3 hrs. The results compare well.

TITLE: On the influence of x-irradiation on certain properties of lithium-fluoride single crystals

SOURCE: Fizika tverdogo tela, v. 8, no. 3, 1966, 680-683

TOPIC TAGS: lithium fluoride, single crystal, x irradiation, color center, crystal defect, dielectric loss, crystal lattice vacancy

ABSTRACT: The purpose of the investigation was to establish a connection between the change in the volumes of the cells of LiF crystals and the occurrence in these crystals of processes which change the dielectric losses. To this end, single crystals of LiF were exposed to x-rays at doses ranging from 2.1 to 86.7 micro-roentgen and their dielectric constant and capacitance measured with an ac bridge (60--20 kcs). The results showed that the crystal lattice constant increased even with the smallest x-ray dose, indicating that irradiation produces not only the appearance of color centers but also of lattice defects which increase the losses.

Card 1/2

L 22061-66

ACC NR: AP6009642

The accompanying decrease in density (measured by a flotation method) can be shown to be due only to a change in the lattice volume. The increase in the lattice constant and the change in the loss angle due to the irradiation are briefly discussed from the point of view of formation of vacancies as a result of ionization. The decrease in conductivity leads to a decrease in the dielectric losses. The authors thank B. P. Konstantinov for help with the work. Orig. art. has: 3 figures, 1 formula, and 1 table.

PURPOSE: This collection of articles is intended for scientific research workers and metallurgical engineers.

COVERAGE: The articles summarize results of experimental studies of titanium-base alloys. The microstructure and mechanical properties of titanium-base alloys containing aluminum, chromium or other metals are analyzed along with the effect of oxygen, hydrogen and heat treatment on alloy structure and properties. The tendency of titanium alloys to embrittlement as a result of strain

Card #16

Titanium and Its Alloys (Cont.)

SOV/4508

aging is emphasized, and the nitriding of titanium, carried out to increase the surface strength and wear resistance of titanium alloys, is described. Transformations occurring in commercial titanium under conditions of electric heating are examined. Attempts to develop titanium-base alloys capable of withstanding temperatures over 400°C are discussed as are problems of titanium-powder metallurgy and weldability of certain titanium-base alloys. No personalities are mentioned. Most of the articles have bibliographic references, the majority of which are Soviet.

TITLE: Titanium Based Metalloceramic Alloys

PERIODICAL: Vestn. metallovedeniya metally, 1980, No 3, pp. 56-74 (03581)

ABSTRACT: The branch of Powdered Metallurgy of the Central Iron and Steel Scientific Research Institute produced titanium based alloys in the form of sintered swivels up to 40 kg which are proposed instead of plates and wire. A pressurized equipment is being introduced for pressing ceramic up to 250 kg in various alloying elements on titanium (Ti-Al-V) accumulated at the Institute is briefly described. The influence of aluminum, vanadium, iron, manganese, tin and niobium on the mechanical properties of Ti-Al-V alloy (strength at +20 and +400°C; reduction in area (RIZ) at +20 and -60°C) is shown in the plot (Fig. 2). Of the titanium alloys for the production of sheet the most systematic investigation was carried out for the ternary system Ti-Al-V. The alloy Ti-Al-V (21 + 35 Al + 2% V) is

being produced; the properties of this alloy are given in Table 1. The composition of an alloy of Ti + 4% Al + 2% V (TiAlV) is proposed for the production of sheet for operation at elevated temperatures (up to 500°C), properties given in Table 2. Alloy for the production of hot rolled tubes, forgings and standard (Al₂O₃) and Ti₂O₃) composition as given in Table 3. After heat working by pressure, between the structure of two stable phases with a small amount of a phase. This makes it possible to limit treatment only to annealing of forged and hot rolled metal. The dependence of hardness of the above alloys on annealing temperature (200 to 600°C) is shown in Fig. 3. The heat resistant alloy Ti + 20% Al and component metalloceramic alloy (composition not given) and was developed for forging and stamping. The dependence of its mechanical properties on temperature is plotted in Fig. 4. Titanium sintered components have strength and plasticity for the following treatment by sintering (with mantle, subsequent machining) were

found to belong to binary systems of Ti-V and Ti-Cr and ternary alloys of these alloys with vanadium. Their compositions and mechanical properties are given in Table 5. Properties of three other related alloys of the Ti-Al system are ternary, obtained, based on the addition of vanadium and aluminum. Susceptibility to oxidation decreases with increasing V (Fig. 5) respectively. Alloys of the Ti-Al system with 25 nickel impurities in sintered form decrease in strength with increasing temperature. Specific gravity (about 3.5 g/cm³) is close to that of molybdenum, therefore they can be used as substitutes for molybdenum in the manufacture of refractory articles. Table 6 gives the properties of refractory articles. References: 300 publications, 200 patent applications.

broaching or rolling is a three-phase one: $\beta + \alpha + \omega$. The quantity of the ω -phase is small and therefore it is not always detected on X-ray diffraction patterns. Under certain conditions eutectoidal transformations and also formation of metastable, β and ω phases are observed. Blanks for the investigations were produced by powder metallurgy methods from titanium powder containing 0.12% Fe, 0.074% Si, 0.12% Ni, 0.022% Al, 0.052% Ca, 0.003% H, 0.18% O, 0.01% N. The sintered blanks were forged into 16 mm diameter rods at 1000 to 700°C. Since titanium alloys of the binary systems Ti-Fe, Ti-Cr, Ti-Mn belong to the eutectoidal systems, the authors considered it of interest to establish the proneness of these alloys to embrittlement after annealing at 400, 500 and 600°C for 100 hours. The mechanical properties of forged rods and rods annealed at 700 and 800°C after heating for 100 hours at 400, 500 and 600°C are given in Table 2, each figure representing the average values of 5 tests. It can be seen from Table 2 that with increasing heating temperature the plasticity of alloy 2 decreases, whilst that of alloy 1 increases. The strength of the forged alloy 1 after 100 hours at 400, 500 and

Card 2/6

S/129/61/000/004/006/012

Structure and Mechanical Properties... E073/E535

600°C decreases, whilst its ductility increases; this is attributed to an increase in the quantity of the α -phase. Heating of the alloy 1 for 100 hours at 400, 500 and 600°C leads to the transformation $\beta + \alpha + \omega \rightarrow \beta + \alpha$. The strength of the annealed alloy 1 after heating for 100 hours at 400-600°C changes insignificantly, but its ductility increases in the case of heating temperatures of 400 and 500°C and decreases for a heating temperature of 600°C. The increased ductility is attributed to an increase in the quantity of the α -phase, which also increases as a result of ageing. The ageing curves of the two alloys after quenching in water from 900°C are plotted in Fig.2, the top graph relates to alloy 1, the bottom graph to alloy 2. These curves indicate that both alloys contain a β stabilizer above the critical value. Whilst at ageing temperatures of 200, 300 and 400°C the rejection of the ω -phase only is observed, in the case of ageing at 500°C formation of the ω -phase followed by formation of the α -phase was observed. There are 2 figures, 2 tables and 6 references: 4 Soviet and 2 non-Soviet.

TITLE: Embrittlement of titanium-chromium alloys during
eutectoidal transformation

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
1961, No.7, pp.35-36 + 1 plate

TEXT: The diagram of state of the Ti-Cr system is characterized on the titanium side by a two-phase region $\alpha + \beta$ and a eutectoidal transformation ($\beta \rightarrow \alpha + \text{TiCr}_2$) (Refs. 1 and 2: P. Duwez, Taylor, I.L., TASM, v.44, 1952; A. D. McQuillan, Journal Institute of Metals, v.80, 1951-1952, respectively). This occurs at 670-675°C and the speed of transformation is extremely slow (Ref. 3: Bagryatskiy, Yu.A., Nosova, G.I., Tagunova, T.V., Zhurnal neorganicheskoy khimii AN SSSR, vol.3, issue 3, 1958). The structure of hypoeutectoidal alloys remains metastable ($\alpha + \beta$) even after annealing. Heating of alloys in the ($\alpha + \beta$) state below the eutectoidal transformation temperature may bring about a decomposition of the β -phase, which is accompanied by embrittlement. The authors studied the influence of long duration holding

X

Card 1/5

26194

Embrittlement of titanium-chromium ... S/129/61/000/007/008/016
E073/E535

at 300 to 600°C on the mechanical properties and the structure of Ti-Cr alloys. Commercially pure titanium IMP-1A (IMP-1A) was used (composition: 0.21% Fe, 0.062% Si, 0.16% Ni, 0.05% N, 0.03% C, 0.05% Ca and 0.2% O). The alloys were produced by powder metallurgy methods. The investigations were made on forged 16 mm diameter rods, which were held for one hour at 730°C, cooled in the furnace and, following that, heated additionally for durations of 1 to 300 hours at 300, 350, 400, 450, 500 and 600°C. It can be seen from the obtained results, which are tabulated, that heating at 300°C for 100-200 hours does not bring about a change in the mechanical properties. Heating at 350°C for 200-300 hours results in a slight decrease in plasticity, i.e. the contraction decreases to 14.3 and 16.1%, respectively from 19.9% in the annealed state. Only a slight increase in strength and hardness were observed. Increase in the heating time at 400°C from 25 to 200 hours leads to a drop in plasticity, the contraction decreasing from 20.9 to 9.9%. The most pronounced embrittlement occurs at 450, 500 and 600°C; holding for one hour at 600°C brings about a drop in the contraction by a factor of 2. The

Card 2/5

21194

Embrittlement of titanium-chromium ... S/129/61/000/007/008/016
E073/E535

authors considered it of interest to study the changes in the microstructure which are associated with embrittlement. The shape of the rejected particles of the α -phase depends on the temperature conditions of the deformation: an "acicular" structure corresponds to terminating the forging above 800°C, a "granular" structure corresponds to a termination of the forging below 700°C. Microstructure photographs are reproduced of an alloy with 5% Cr and an "acicular" structure after annealing and after additional holding at 500°C for 100 hours; the additional holding at this temperature produces darkened sections of the β -phase. X-ray structural investigations (carried out by Candidate of Technical Sciences T. V. Tagunova) have shown that in the annealed state the alloy has a two-phase $\alpha + \beta$ structure. After additional holding at 350°C for 100 hours, the β -phase lines become weaker and at 500 to 600°C they cease completely. No lines of the corresponding intermetallic $TiCr_2$ compound were detected in this case. The microstructures of alloys with 10, 15 and 20% Cr revealed darkened β -phase sections after annealing, followed by subsequent heating, whereby for alloys with a higher chromium

Card 3/5

Embrittlement of titanium-chromium... 24194
S/129/61/000/007/008/016
E073/E535

concentration a eutectoidal structure could be observed. In this case the X-ray patterns revealed lines corresponding to the $TiCr_2$ compound which were most clearly visible on alloys with 15 and 20% Cr. In these alloys eutectoidal β -phase decomposition is accompanied by an appreciable increase in hardness. Table 2 shows the hardness of alloys with 10 to 20% Cr.

Table 2

Chromium content in %	H_{RC} after annealing at 1000°C	H_{RC} after annealing at 600°C for 100 hours
10	32	34
15	37	39
20	39	43

The data given prove that embrittlement of an alloy containing 5% Cr after long duration soaking below the eutectoidal temperature is due to eutectoidal β -phase transformation. Absence of lines corresponding to the $TiCr_2$ compound in an alloy containing 5% Cr is explained by the inadequate sensitivity of the X-ray method. There are 3 figures, 2 tables and 3 references:

TITLE: Dilatometric studies of binary titanium-base alloys

PERIODICAL: Metallovedeniye i termicheskaya obrabotka metallov,
no. 2, 1963, 32 - 36

TEXT: Dilatometric curves were constructed in the 20 - 900 °C range for the binary Ti-Fe, Ti-Cr, Ti-Co, Ti-Mo, Ti-V, Ti-Nb and Ti-Ta alloys containing 2-10% of the alloying elements, the constitution of these alloys was determined by metallographic and X-ray diffraction analysis, and the hardness of the alloys after various heat-treatments was measured. Experimental test pieces were prepared by powder metallurgy. No deflection points were observed on the dilatometric curves in the case of specimens annealed by heating to 800 or 900 °C with slow cooling; the slope of the curves was constant, indicating that the coefficients of thermal expansion of the alloys studied in the annealed condition were constant. The hardness of the annealed alloys was either equal to or higher than that of the specimens quenched from the β -range,

Dilatometric studies

the effect of the alloying-elements content (%) on the hardness (HRC) of the quenched alloys being shown in Fig. 1. The dilatometric curves of alloys with a sufficiently high content of elements stabilizing the β -phase (Fe, Cr, Co) had deflection points in the temperature range of the ω -transformation. The alloy with the critical (4%) concentration of Fe had in the quenched condition a two-phase ($\beta + \omega$) structure and high (RC 51.5) hardness. The dilatometric curve of this alloy showed no contraction associated with the formation of the ω -phase and the expansion due to a reversible $(\beta + \omega) \rightleftharpoons (\beta + \alpha)$ transformation started at 420 and ceased at 490 $^{\circ}\text{C}$. In the case of the quenched alloy with 6% Fe, consisting of the β -and partially precipitated ω -phases (hardness 44.5), the ω -phase was precipitated completely on heating, as a result of which the hardness of the alloy increased to RC 53; the dilatometric curve showed a contraction associated with the $\beta \rightarrow \omega$ transformation in the 170 - 400 $^{\circ}\text{C}$ range and an expansion in the 475 - 500 $^{\circ}\text{C}$ interval, where the $(\beta + \omega) \rightleftharpoons (\beta + \alpha)$ transformation took place. The hardness of quenched alloys with 8% Fe, consisting of the stabilized β -phase, increased on heating from 41.5 - 53. The small contraction and expansion on the dilatometric curve of Card 2/4

E193/E585

Dilatometric studies

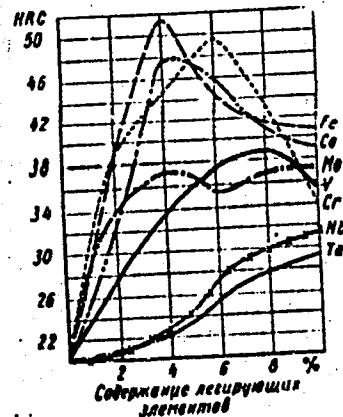

this alloy indicated only a partial precipitation of the ω -phase. Similar effects were observed in the Ti-Cr alloys in which, however, the volumetric changes were less pronounced; the critical Co content was about 3.5% in the case of the Ti-Co alloys. X-ray diffraction analysis showed that quenched specimens of the 4% Co-Ti alloy had a two-phase structure (β - and partially precipitated ω -phase); the precipitation of the ω -phase in this alloy on heating (indicated by an increase in hardness from 48 - 50 RC) was, for some unknown reason, not reflected by deflection points on the dilatometric curve. In the case of the Ti-Mo alloys the volumetric effect was observed in the 10% Mo alloy only, indicating that the ω -transformation did not take place in alloys containing 2 - 8% Mo. No deflection points were observed on dilatometric curves for the Ti-V, Ti-Nb and Ti-Ta alloys. This was attributed to the fact that the ω -phase in these alloys could be formed only at a high concentration of the alloying elements (12 - 15% V, 23 - 30% Nb and 26 - 40% Ta). There are 3 figures and 1 table.

TITLE: Mechanical properties and microstructure of sintered titanium alloys

27

SOURCE: Poroshkovaya metallurgiya, no. 3, 1963, 88-98

TOPIC TAGS: sintered titanium alloys, mechanical properties, microstructure, grain size, alloying element effect, Fe, Mn, Cr, Mo, Al, V, Ti, Ta, Nb, Cu, Zr, Co, Ti-Al-V alloy, Ti-Al-V-Mo alloy, coreduction, oxide

ABSTRACT: Several series of binary and ternary alloys of Ti with Al, Fe, Mn, Cr, Mo, W, V, Ta, Nb, Cu, Zr, and Co were sintered from commercial-grade (99.1% pure) Ti powder and powders of 99.6% pure Fe, 99.5% pure Mn, 99.6% pure Cr, 99.54% pure Ni, 99.2% pure Co, electrolytic Cu, 99.9% pure W, 99.65% pure V, 99.6% pure Ta, and 99.9% pure Cu. The Ti-Al alloys and the second series of Ti-V alloys were prepared by coprecipitation of oxide powders with calcium hydride. Sintered specimens had a coarse, acicular microstructure, macrograins about 1 mm in diameter, and a density of 97-99% of the theoretical. The results of mechanical tests (see Figs. 1 and 2 of Enclosure) show that all the alloying elements investigated increase the tensile strength

Card 1/8-2

- 7. (2/55) -

L 11288-63

ACCESSION NR: AP3001956

and decrease the ductility of sintered Ti alloys. Only in Ti-V alloys produced by coreduction of oxides does ductility increase with increasing V content. These alloys generally are more brittle than commercial titanium. The strong S-phase stabilizers, Fe, Mn, and Cr, which produce eutectoid transformation with the formation of intermetallic compounds, also have the highest decreases in tensile strength and decreases in ductility in sintered Ti alloys.

In general, Ti-Mn, Ti-Cr, and Ti-Al alloys containing > 1% of alloying elements have a metastable $\alpha + \beta$ structure with the amount of the β -phase increasing with higher alloying; the α -phase has an irregular Widmanstatten structure. Aluminum, an α -phase stabilizer, appreciably increases the strength of sintered Ti-Al alloys without an extensive decrease in ductility. The Ti-V and Ti-Mn alloys have comparatively high tensile strength and ductility. In general, V, Al, and Mn were found to be the best alloying elements for sintered binary Ti alloys. Additional investigation of sintered Ti-Mn alloys (obtained by coreduction of the oxides) showed the Ti + 4% Al + 10% Mn alloy to have the best combination of mechanical properties: tensile strength 357.5 Mn/m² (meganewton per square meter, 1 Mn/m² = 0.1 kg/mm²), elongation 1%, reduction of area 4%, and notch toughness 25.4 joule per cm² (1 joule/cm = 0.1 m-kg/cm). An addition of 2% Mo to this alloy increases its tensile strength to 397.5 Mn/m² without lowering ductility. These two alloys are recommended for manufacturing parts by

TITLE: Properties and microstructure of sintered Kh18N15 stainless
steel made by joint reduction method

SOURCE: Poroshkovaya metallurgiya, no. 3 (21), 1964, 50-63

TOPIC TAGS: stainless steel, sintered stainless steel, carbonyl
iron, sintered steel property, steel corrosion resistance, sintered
steel structure

ABSTRACT: Investigations have been made of the properties of
sintered Kh18N15 chromium-nickel-stainless steel made from powder
produced by the joint reduction of chromium and nickel oxides
mixed with iron powders (Process A) and of steel made from mechani-
cally mixed powders of carbonyl iron, reduced chromium, and electro-
lytic nickel (Process B). It was found that the density of compacts
A was lower than that of B, but the latter had a very low compression
strength. Adequate fluidity of powders and strength of compacts

Card 1/3

ACCESSION NR: AP4040471

make powder A a very suitable material for rolling porous strips and sheets in continuous rolling mills. Compacts B sinter more easily than compacts A, but they are much more susceptible to oxidation during the sintering. Compacts A, sintered at 1350°C for 10 hr; had a density of 96—97% (compared to 71—85% for compacts B), tensile strength 47.8—53.5 kg/mm², elongation 29.2—43.4% and impact toughness (unnotched specimens) 19.8—29 kgm/cm². Sintered Kh18Ni5 steel has an austenitic structure with a low content of finely dispersed carbides. In the annealed state the steel has a high corrosion resistance; its corrosion rate in boiling 65% nitric acid is 0.1 g/m² · hr compared to 0.2 g/m² · hr for conventionally made X18H15. This is explained by a low content of impurities in powder A. Orig. art. has: 8 tables and 9 figures.

TITLE: Powdered-metal stainless chrome and chrome-nickel steels 16

SOURCE: Moscow. Tsentral'nyy nauchno-issledovatel'skiy institut chernoy me-tallurgii. Sbornik trudov, no. 43, 1965. Poroshkovaya metallurgiya (Powder metal-lurgy), 81-98

44.55
TOPIC TAGS: powder metallurgy, stainless steel, chromium steel, nickel steel, corrosion resistance

ABSTRACT: It is shown that the powders of stainless chrome and chrome-nickel steels in the ferritic, austenitic, and martensitic-austenitic classes, prepared by the method of the combined reduction of metal oxides by means of CaH₂, are suitable for the industrial fabrication of porous and compact sheets and strips by the direct method of powder rolling. The flowsheet of production of these powders has the following sequence: raw materials -- iron powder (carbonyl and other types of Fe), chromium oxide (Cr₂O₃), nickel (electrolytic, carbonyl)

Card 1/3

L 2847-66

ACCESSION NR: AT5022891

2

powder or NiO, Ni_2O_3 , calcium hydride (CaH_2); charge blending (2.5 hr); reduction at 1175°C for 6-8 hr, $\text{Cr}_2\text{O}_3 + 3\text{CaH}_2 = 2\text{Cr} + 3\text{CaO} + 3\text{H}_2$; crushing of sinter; slaking with H_2O and pulverization; hydrocyclone treatment of pulp; leaching -- $\text{Ca}(\text{OH})_2 + 2\text{HCl} = \text{CaCl}_2 + 2\text{H}_2\text{O}$; washing to remove CaCl_2 ; centrifuging; vacuum drying, $60-70^\circ\text{C}$. Sintered stainless steels display high physical properties, which warrants recommending them for the fabrication of the elements and devices performing in aggressive media. When pressed under a pressure of 10 t/cm^2 and subjected to deformation and heat treatment, powdered-metal stainless steels are not inferior to steels produced by the smelting method as regards their physical properties and corrosion resistance. Thus, for example, corrosion tests of Kh18N15 stainless austenite steel in a 65% solution of boiling HNO_3 demonstrated the high corrosion strength of this steel, not inferior to that of deformed cast steel (corrosion rate $0.1-0.16 \text{ g/m}^2\text{-hr}$). Evidently these good qualities of powdered-metal stainless steels are attributable to the low content of impurities in the powders prepared by the combined oxide reduction method. TITLE: Investigation of the properties and production conditions of nichrome powder

SOURCE: Moscow. Tsentral'nyy nauchno-issledovatel'skiy institut chernoy metal-lurgii [Sbornik trudov, no. 43, 1965. Poroshkovaya metallurgiya (Powder metallurgy), 99-108]

TOPIC TAGS: nichrome alloy, powder alloy, nonmetallic inclusion, sintering, solid solution, twinning, heat resistant alloy, resistivity

ABSTRACT: In view of the deviations observed in the technological properties of the products fabricated from the powder of Kh20N80 nichrome alloy prepared by the method of the combined reduction of metal oxides with CaH₂ developed by the Central Scientific Research Institute of Ferrous Metallurgy, the authors performed a thorough investigation of the parameters of the process. Gas analyses and metallographic examinations established that nichrome powders obtained at

Card 1/3

L 2679-66

ACCESSION NR: AT5022892

oxide-reduction temperatures of 900-1100°C (for 6 hr) contain a considerable amount of non-metallic inclusions, associated with the higher content of oxygen. This condition is corrected (the oxygen content is reduced to the required minimum of 0.4% and the microstructure becomes homogeneous) by raising to 1175°C the reduction temperature and performing reduction for 6-8 hr (6 hr for 219-mm diameter retort and 8 hr for 273-mm diameter retort). However, while the powder prepared at 1175°C for 6-8 hr displays the optimal compactibility, its sinterability is much lower than in powders prepared at lower reduction temperatures (900-1100°C), which evidently is attributable to the activating effect of oxygen as well as to granulometric composition. Since, the oxygen content may not exceed 0.04%, it appears that sinterability can be improved only by altering the granulometric composition of the powder. This composition can be regulated within broad limits by pulverizing the sinter (pulp) for 0.5, 1.0, 1.5, and 2 hr. To evaluate its quality, the powdered-metal nichrome prepared on the basis of the above improvements was subjected to heat treatment and cold working and tested for physical properties. Specimens compacted under a pressure of 6.0-6.8 tons/cm² and sintered at the maximum temperature (1375°C) were found to display the highest ultimate strength and plasticity. Wire of 0.5-2.0 mm diameter fabricated from sintered briquets displays, following its heat treatment (water quenching from

Card 2/3

L 2679-56

ACCESSION NR: AT5022892

870°C), physical properties as high as those of standard nichrome wire. Following its sintering, as well as following its forging in the temperature range 1000-1200°C, the powdered-metal nichrome has the monophase structure of a nickel-base solid solution with grain boundaries clearly revealed by etching. Following its annealing at 800 or 900°C the nichrome displays the typical structure of nickel austenite; the grain orientation changes and a large number of twins appears. In addition to their high heat resistance and resistance to oxidation at high temperatures, the products fabricated from such nichrome powder display a high resistivity (1.07-1.12 ohm-mm²/m). TITLE: Investigation of the microstructure of alloy powders obtained by the combined reduction method

SOURCE: Moscow. Tsentral'nyy nauchno-issledovatel'skiy institut chernoy metal-lurgii. Sbornik trudov, no. 43, 1965. Poroshkovaya metallurgiya (Powder metallurgy), 109-114

TOPIC TAGS: metal powder, alloy powder, nichrome alloy, grain structure

ABSTRACT: The process of the combined reduction of metal powders and oxides by means of CaH₂ usually takes place in the solid phase, and then the granulometric composition of the resulting powder is chiefly determined by two factors: 1) physical properties of raw materials; and 2) the process of agglomeration of the metal particles (this process takes place in the solid phase for both fine- and coarse-grained materials). Studies of a large number of industrial batches of the powder of Kh20N80 nichrome established that distinct structural inhomogeneities appear only when the technological regimes of production are disregarded. Such

Card 1/3

L 2680-66

ACCESSION NR: AT5022893

5

inhomogeneities are manifested in the form of the presence of a second phase although no such phase was revealed by radiographic examination. A microscopic examination of the Sulin and Tula iron powders revealed, along with particles having ferrite structure, isolated particles with ferrite + pearlite structure conditioned by a higher content of C. Such nonuniformity of individual particles as regards C content also persists in Kh18N15 steel. Particles with two-phase structure have been observed in individual industrial batches of Fe-Al master alloy powder which indicates violations of the technological régime of charge blending, mixing, and reduction. The microstructural inhomogeneity of the powder of Kh18N15 steel, conditioned by its content of alloy elements, is greater if the comparatively coarse-grained Sulin and Tula iron powders are used as part of the raw materials. In this case an appreciable amount of α -phase is observed in the microstructure of the large particles. If, on the other hand, this steel, as well as Kh20N80 nichrome alloy, is prepared from fine-grained raw materials, the resulting powders will display some inhomogeneity with respect to the content of alloy elements, owing to their extremely weak ferromagnetic properties. All this, however, is no reason for rejecting the powders as defective, since, being chiefly destined for processing into metallurgical products, they are subjected to sintering, which involves complete homogenization of their composition.

conifer and broad-leaved). The content of broad-leaved pollen in the middle part of the section is 16% (more than in drill-hole No. 1). From a study of the pollen, the author has marked out the principal stages in the plant history of the region: 1) a stage of spruce-pine forests; 2) a stage of birch forests, with the broad-leaved varieties becoming more abundant; and 3) a stage of spruce-pine forests. Comparison of the proposed sequence with that proposed for the Holocene of the Middle Urals and the Molotovskoye Prikam'ye (Kama River region near Molotov) indicates a common outline. The author thus refers the deposits described in the present report to the Holocene.

ABSTRACT:

The composition of the spore-pollen spectra of the Quaternary sediments of many Northern districts shows that during the Quaternary birches played a substantial part in the formation of the flora. While studying these spectra in the Northern part of the West Siberian plains, the author of the paper under review felt it necessary to determine also the birch species. The reason for this is the fact that solely determinations of the genus of the pollen as far as the genus is concerned do not make it possible to determine the flora type correctly. The relative climatic changes in this area found their expression in changes in the types of the forest and of the tundra. On the basis of the rich occurrence of

20-114-3-53/60

birch pollen alone it was difficult to decide whether the spectra under investigation reflected forests or an open landscape. Among birches there exist both trees and shrubs, among the latter some are small as, for instance, the *Betula nana*. Determination of the species of the birches has often made it necessary to modify earlier conclusions and thus either to obtain a more accurate picture, or to revise the existing picture, of the stratigraphic position of the one or the other level. The author of the paper under review succeeded in determining the pollen of *B. pubescens*, *vurrucosa*, *nana* and *humilis*. In such a determination, it is essential to pay great attention to the entirety of the morphological characteristics. The size of the pollen, being dependent on different causes and being most variable, is less important. The author of the present paper employed in her investigations the acetolytic working method (mixture of acetal aldehyde and sulphuric acid). The present paper lists some examples in order to demonstrate the necessity of determining the species. In cases of poor preservation where it is impossible to determine the species it would be necessary at least to single out sections, as in this case *Nanae*

<p><i>C</i></p> <p>Colorimetric determination of copper with the sodium diethyldithiocarbamate reagent. M. Golubeva, <i>Gizgaz i Sint.</i> 11, No. 5, 29-33 (1946). The method of Callan and Henderson (C.I., 24, 312) gave good results in the detn. of Cu in humin-colored natural waters and, with certain modifications, also in water contg. Fe, Al, Zn, and Pb. The water was almost decolorized (the original color value decreased from 40 (0) to 2-6) by treatment with an Al(OH)₃ soln. and alkalization. The pH should be 4.1-4.8; variation to 3.0 or 5.0 causes adsorption of Cu by the excess Al(OH)₃ formed in the reaction. Treatment with (NH₄)₂SO₄ lowered the color value from 40 (0) to 2-4 without affecting accuracy. Resins of Rochelle salt, used to remove both Fe and Al, does not affect the results. Removal of Fe and Al as hydroxides (as suggested in the original carbamate procedure) leads to loss of Cu during filtration owing to adsorption. When water contains Zn or Pb, a white ppt. or turbidity develops on addition of the carbamate reagent. In presence of Rochelle salt and starch no ppt. or turbidity appears at Zn and Pb concns. of 100 and 1 mg./l. Addn. of a 25% NH₄ soln. instead of the 1:5 diln. prescribed in the original procedure, permits a Zn content up to 1000 mg./l. without affecting the analysis. To a 50-cc. sample of water add one cc. of a 80% Rochelle salt soln., 5 cc. of NH₄ soln. (1:5), 1 cc. of a clear 0.5% soln. of starch, and 8 cc. of a 0.1% NH₄ soln. of Na diethyldithiocarbamate. Mix after each addn. and compare with a standard contg. 0.01-1.0 mg./l. of Cu. To decolorize the water, introduce into an Erlenmeyer flask 50 cc. of sample, Add 2.5 cc. of a 20% (NH₄)₂SO₄ soln., dil. with H₂O to 70-80 cc., and boil 30-60 min., until the water is colorless and the precipitate is decomposed. Transfer to a Nessler cylinder. Dil. dil. to 50 cc. Treat as above and compare with standard. In the presence of Zn (over 100 mg./l.), replace the dil. NH₄ by 5 cc. of a 25% soln. In the presence of Pb (over 1 mg./l.), place a 100-cc. sample of water in a tall cylinder, add 4 cc. of a 25% NH₄Cl soln. and 1 cc. of N CuCl₂, then 10 cc. of a 25% NH₄ soln. and 1 cc. of N Na₂CO₃. Stir and let stand until the ppt. settles. Siphon off the supernatant fluid and det. Cu in this soln. as above, except that NH₄ is not added. Correction must be made for diln. in removal of Pb. C. S. The reciprocal system of chlorides and sulfates of lithium
and calcium. M. S. Ingel'son and A. G. Il'inskaya. State
Electrochemical Institute, Moscow, USSR.

The reciprocal system of the salts and the citrates
of lithium and calcium that represents the reciprocal system
of the salts of the alkali metals, which is reflected in the diagram
of the areas of the stability of the following binary systems:
LiCl-Li₂SO₄, Li₂SO₄-CaCl₂, Li₂SO₄-Ca₂(SO₄)₃,
Li₂SO₄-Ca₃(PO₄)₂, Li₂SO₄-Ca₃(AsO₄)₂, Li₂SO₄-Ca₃(PO₄)₂·Ca₃(AsO₄)₂,
Li₂SO₄-Ca₃(AsO₄)₂·Ca₃(PO₄)₂. There are also
indicated the areas of the stability of the citrate systems:
Li₂Cl-Ca₃(AsO₄)₂·Ca₃(PO₄)₂, Li₂Cl-Ca₃(AsO₄)₂,
Li₂Cl-Ca₃(PO₄)₂.

✓ Irreversibly reciprocal system of chlorides and sulfates of lithium and strontium. M. S. Golubeva and A. G. Bergman (State Univ., Rostov-on-Don). 32nd Obschei Khim 23, 458-63 (1955); J. Gen. Chem. U.S.S.R. 25, 427-

32 (1955) (Engl. translation).—The system is irreversibly reciprocal without complex formation. According to the magnitude of the thermal effect (0.47 kcal./g. equiv.) the system should be reversible, but exptl. data are to the contrary. There is also a discrepancy between the direction of exchange reaction shift and thermal effect. The exptl. shift is in the direction of $\text{SrSO}_4\text{-LiCl}$. There is great similarity to the Li, Ca(Cl, SO_4) systems because of similar ionic radii, charges, and structure of electron layers

TITLE: The Melting Diagram of the Ternary Systems of Sodium- and Potassium Acetates, Rhodanides and Thiosulphates

PERIODICAL: Zhurnal neorganicheskoy khimii, 1959, Vol 4, Nr 11, pp 2606-2610 (USSR)

ABSTRACT: The reason for investigating these systems was the necessity of finding low-melting baths for sulphidizing the surface of metal products. The binary system $(\text{NaCNS})_2 - (\text{CH}_3\text{COONa})_2$ forms a eutectic. The binary systems $(\text{NaCNS})_2 - \text{Na}_2\text{S}_2\text{O}_3$ and $(\text{CH}_2\text{COONa})_2 - \text{Na}_2\text{S}_2\text{O}_3$ could not be investigated since the components decompose on heating before they are melted. The ternary system $\text{Na}^+ \parallel \text{CNS}^-$, $\text{S}_2\text{O}_3^{2-}$, CH_3COO^- (Table 1, Figs 1, 2) has three crystallization fields of its components meeting in the eutectic point at 222° and the composition of 32% $(\text{CH}_3\text{COONa})_2$, 40% $(\text{NaCNS})_2$, 28% $\text{Na}_2\text{S}_2\text{O}_3$. In the binary system $(\text{KCNS})_2 - (\text{CH}_3\text{COOK})_2$, the compound $2\text{KCNS} \cdot \text{CH}_3\text{COOK}$ melting at 134°

is formed. The system $(KCNS)_2 - K_2S_2O_3$ could only be investigated - because of decomposition of the organic component on heating - up to a content of 35% $K_2S_2O_3$, the system $(CH_3COOK)_2 - K_2S_2O_3$ only up to a content of 25% $K_2S_2O_3$. The ternary system $K^+|| CNS^- , S_2O_3^{2-} , CH_3COO^-$ (Fig 3, Table 2) forms four crystallization fields, three of the components and one of the compound $2KCNS \cdot CH_3COOK$. The two ternary systems could not be completely investigated either, since the thermal stability decreases with an increasing thiosulphate content, and decomposition occurs. There are 5 figures, 2 tables, and 2 Soviet references.

Colorimetric determination of aluminum with
hematoxylin. M. T. Gorunava. J. Appl. Chem.
Rom., 1963, 6, 1144-1149.---Hattfield's method (A,
1934, II, 320) gives satisfactory results with coloured
as well as colourless hematoxylin. It serves for
determination of 0.003-0.5 mg. of Al per litre of H₂O
(error $\pm 5\%$). Cu and Mg affect the colour obtained.
Low results are obtained when the Al is in the form of
hydroxide.

The residual aluminum. B. A. Skopintsev and M. T. Golubeva, *Vodosnabжение и Sanit. Tekh.* 15, No. 7; 40-4 (1960).—The residual Al entering the water supply is the result of unsatisfactory coagulation. Insufficient alum will favor the formation of stable colloidal Al(OH)_3 , and an excess will retard the flocculation; this reduces pH to below 8.0 and causes partial soln. and insufficient utilization of the coagulant. Low temp. will also cause residual Al. Where lime is added, careful dosing is important. Increased pH above 7.0 will lead to the formation of solid aluminates. References. B. Gutoff
