TITLE: Mechanical properties of germanium as a function of carrier concentration

PERIODICAL: Fizika tverdogo tela, v. 3, no. 12, 1961, 3650 - 3656

TEXT: The variation in microhardness of the surface layer of germanium with varying concentration of free carriers has been studied. The microhardness was measured with a UMT-3(PMT-3) instrument at loads of 3 - 5 g. The indentations were measured with an immersion objective (2000 $\times$ ) in order to reduce the error in measurement. The carrier concentrations were changed by irradiating the germanium surface with light of varying intensity. 300-w motion-picture lamps circularly arranged at a distance of 10 cm from the specimen were used for the purpose. A maximum light intensity of 50,000 lux was reached. It was lowered by removing some reflectors and lamps. Fans prevented the specimens and lamps from heating. The carrier concentration was also changed by carrier injection from point

Mechanical properties of ...

contacts. For this purpose, a plate with probes was attached to the PMT-3 instrument in such a way that the probes were regularly arranged around the point where the indentor penetrated into the specimen. Preliminary experiments have shown that at a stress of 3 - 5 g the indentations are entirely in the layer ( $1 - 2 \mu$ ) where the photomechanical effect occurs. The experiments have indicated that the variation in hardness of the germanium specimen is due to the variation in carrier concentration (Fig. 2), no matter how the carriers are introduced into the semiconductor. The variation in hardness must therefore be related to a variation in dislocation density or mobility. It is concluded from the results that it is the dislocation mobility that varies. After irradiation with 40 - 50,000 lux for several hours, the properties of the surface layer passed over into a new state, in which the indentations were surrounded by bright and dark rings ("aureoles") which vanished after holding at room temperature or in boiling water for several hours. The aureoles are now being examined. V. N. Dobrovel'skiy is thanked for discussions. There are 5 figures, 1 table, and 5 references: 1 Soviet and 4 non-Soviet. The three references to English-language publications read as follows: G. C. Kuczinski and

TITLE: The photomechanical effect in antimony

PERIODICAL: Fizika tverdogo tela, v. 4, no. 10, 1962, 2656-2659

TEXT: Earlier studies (G. C. Kuczynski, R. H. Hochman. J. Appl. Phys., 30, 267, 1959) revealed a photomechanical effect (reduction in microhardness) in germanium in the range of intrinsic absorption ( $2 - 4\mu$ ). Attempts were made to find out whether this effect occurs in other materials with similar intrinsic absorption bands, e. g. in Sb or Bi. To study this effect in antimony, small specimens of high purity (99.999%)

were hardness-tested at an approximately constant temperature of  $15-16^{\circ}\text{C}$  using a ПМТ-3 (PMT-3) device with a diamond pyramid. The microhardness was found to decrease linearly with the intensity of light in the visible and near infrared region used for illuminating the sample. This decrease, however, continues only to about 30,000 lux, and the microhardness which up to there has dropped by 45% remains constant at higher illuminances. Tests with filtered light showed that the

Card 1/2

The photomechanical effect in antimony

S/181/62/004/010/003/063  
B108/B186

photomechanical effect is due only to infrared radiation, which proves some semiconducting property of antimony. The infrared light transfers electrons to higher energy levels thus changing the dislocation mobility and, consequently, also the mechanical properties of antimony. Careful examination of Cu revealed no photomechanical effect. There are 4 figures.

Photomechanical effect in cadmium sulfide.

SOURCE: IVUZ. Fizika, no. 4, 1964, 12-13

TOPIC TAGS: cadmium sulfide, microhardness, temperature dependence, frequency dependence, carrier density

ABSTRACT: Changes in plastic properties of cadmium sulfide (such as microhardness under the influence of illumination) were investigated to check whether this photomechanical effect could be observed in materials having an absorption band which is excited by the excitation (germanium, antimony, titanium) is indeed due to the excitation of the carrier. For this purpose the surface microhardness of a thin surface layer. The test equipment and methods are described. The tests show that the surface microhardness performed

Card 1/3

L 13816-5  
ACCESSION NR: AP4043864

by approximately 40% when the surface receives an integral illumination on the order of 40,000 lux. This confirms the presence of the photomechanical effect in CdS. Tests of the frequency dependence of the effect have shown it to occur only in the region of intrinsic absorption. Orig. art. has: 3 figures.

TITLE: The temperature range of the existence of the photomechanical effect.

SOURCE: Fizika tverdogo tela, v. 6, no. 5, 1964, 2580-2612

TOPIC TAGS: solid state physics, photomechanical effect, temperature range, hardness, germanium, antimony, extrinsic conductivity, dislocation

ABSTRACT: An attempt is made to determine the conditions under which the photomechanical effect occurs by means of investigating hardness as a function of the temperature of illuminated germanium and antimony. According to the authors, the photomechanical effect which they observed not only in semiconductors but also in metallic materials must be connected with changes in the electronic structure. They consider this firmly established by their own earlier experiments (FTT, 3, 1961; 3650; FTT, 4, 1962; 2656; UFZh, 8, 1963, 1) and by the work of other Soviet researchers (V. N. Beylin, Yu. Kh. Valkilov, FTT, 5, 1963; 2372; T. A. Kontorova, FTT, 4, 1962; 1328; M. S. Ablova, A. R. Regel', FTT, 4, 1962; 1051; V. V. Zhdanova, FTT, 5, 1963, 3341). In particular, they connect the phenomenon with a photon-

cord 1/3

L 8P49-p5  
ACCESSION NR: AF4C4924

induced rise in dislocation mobility, the mechanism of the process remaining still unexplained. In their last experiments, changes in the hardness of n-type germanium and of antimony samples were measured in a temperature range of ~60 to 220°C for Ge, and of 0 to 144°C for Sb, under 30,000 lux illumination, and in the absence of light. The measurements showed that until a certain critical temperature is reached — about 130 to 140°C for Ge and 60°C for Sb — the hardness of the illuminated samples is independent of, or only slightly dependent on, the temperature, while in the same temperature range, the hardness of the unilluminated samples is temperature dependent. The previously insignificant dependence of the illuminated samples on temperature becomes noticeable only in the region where the two curves merge, that is, at reaching the critical temperature. At temperatures higher than

the critical, the increase in hardness of the illuminated samples is much more rapid than that of the unilluminated.

In addition to the decrease in the hardness of the samples with increasing temperature, one of these causes acts as the only factor in the case of temperature changes as well, as in the case of a change in the illumination intensity, and at temperatures higher than 140°C—light off. This factor is the change in the resistance of the samples. As to the origin of this phenomenon, it is difficult to say definitely, but it may be a result of the passage through the critical temperature.

L 5049-65  
ACCESSION NR: AP4044924

which occurs at 100-110°C in the case of germanium, that is, when a temperature dependence of the illuminated sample begins to show before the merging of the two curves. Orig. art. has 3 figures.

TITLE: The photomechanical effect in crystals and its physical nature

SOURCE: AN UkrSSR. Mekhanizm plasticheskoy deformatsii metallov (Mechanism of the  
plastic deformation of metals). Kiev, Naukova dumka, 1965, 96-105

TOPIC TAGS: photoeffect, semiconductor crystal, IR radiation, germanium, cadmium  
sulfide, antimony, titanium, hardness

ABSTRACT: The authors study the photomechanical effect (a reduction in the hardness  
of a material under illumination at room temperature) in n- and p-Ge, dislocation-  
less n-Ge, CdS, antimony and titanium.<sup>18</sup> The microhardness of the specimens was meas-  
ured as a function of illumination intensity. The curves for n- and p- germanium  
and dislocationless germanium are all similar. The change in hardness for p- germa-  
nium is approximately 1/2 that for n- germanium. The surface hardness of n-  
<sup>18</sup>  
<sup>2</sup>

Card 1/2

L 24453-66

ACC NR: AT6010577

germanium decreases with an increase in illumination by approximately 57-60%, while that of p- germanium changes by 40%. The curves show saturation at approximately 20,000 lux. The softened layer extends to a depth of 1-2  $\mu$ . The photomechanical effect takes place only in the infrared region of the spectrum where the natural absorption region lies. The surface hardness of cadmium sulfide is reduced by approximately 40% with an increase in illumination intensity. Saturation begins at approximately 40,000 lux. The photomechanical effect in antimony reaches 45% with saturation at 30,000 lux. The depth of the softened layer is approximately 3  $\mu$ . Titanium shows an effect of 30% with saturation at 25,000 lux. The depth of the softened layer is 2.6  $\mu$ . The effect takes place in the infrared region of the spectrum in all specimens except cadmium sulfide. This is probably due to the fact that acceptor levels of dislocations in CdS lie rather deep with respect to the bottom of the conduction band, as distinct from germanium. A curve for microhardness in n-germanium as a function of current carrier concentration shows that an increase in current carriers reduces microhardness. It is suggested that a study should be made of the magnitude of the photomechanical effect as a function of light frequency.

TITLE: Photomechanical effect in germanium doped with weakly soluble elements

SOURCE: Fizika tverdogo tela, v. 8, no. 6, 1966, 1732-1738

TOPIC TAGS: germanium, hardening, photomechanical effect

ABSTRACT: The purpose of the investigation was to clarify the physical nature of the decrease in hardness of illuminated Ge, in view of the lack of information on the influence of impurities on this process and the lack of systematic research on the influence of impurities on the hardness of Ge in general. Tests were made on samples containing small concentrations of Sb, In, and Ga, and also on Sb containing Ge as an impurity. The Ge host in all tests was standard single crystal with carrier density not higher than  $5 \times 10^{13} \text{ cm}^{-3}$ . The photochemical effect was measured with the PMT-3 instrument using a procedure described elsewhere (Izv. Vuzov. Fizika, No. 4, 22, 1964). In all cases it was found that the decrease in the hardness of the illuminated surface was strongly dependent on the amount of impurity. When the impurity concentration reached the solubility limit, the photomechanical effect decreased to zero. The character of the impurity had no influence, within the limits of errors, on either the characteristics of the photomechanical effect or the microhardness of the samples in darkness. It is therefore concluded that the governing factor in the

Card 1/2

ACC NR: AP6018534

properties of Ge is the quantity and not the type of impurity. In view of the complicated nature of the phenomenon, however, the authors caution that the results should be regarded only as preliminary. Orig. art. has: 8 figures and 2 tables.

PERIODICAL: Priroda, 1958, Nr 6, p 101-102 (USSR)

ABSTRACT: The author has been conducting extensive research work on the lungs and bronchi of dolphins. He found that the walls of their bronchi are provided with ring-shaped interceptors for contraction, which alternate with spheric bulges (widenings). The narrow portions of the bronchi are controlled by powerful muscle bunches, while the bulges are fortified by cartilage plates. These devices enable dolphins to store air in their lungs and to resist water pressure as well as the possible penetration of water into their lungs.

PERIODICAL: Nauka i zhitya, 1957, Nr 12, pp 21-24 (Original in Ukrainian)

ABSTRACT: There are 20,600 km of railroads in the Ukraine with a freight turnover as high as 153 billion ton/km per year. Electrification of these railroads would tend to increase the freight turnover and to facilitate rural electrification. Technical advantages of electric traction and electric locomotives are indicated. It is expected that 30% of all Ukrainian railroads will be electrified by 1970. Transportation data for the Ukraine is given.

TITLE: Effect of some monomers on the biofunctions of  
irradiated yeast cells

PERIODICAL: Radiobiologiya, v.2, no.4, 1962, 539-542

TEXT: This study is the continuation of previous ones. Saccharomyces vini (strain Megri-139-H) were irradiated with a  $\gamma$ -Co<sup>60</sup>-400 (G $\gamma$ -Co<sup>60</sup>-400) apparatus at a dose rate of 1250r/min. The total dose was 12.5-75cu. The survival rate after irradiation and treatment with monomers was determined by the number of colonies. The monomers were vinylpyrrolidone (VP) acrylonitrile (AN) and acrylamide (AA). The concentrations of the aqueous solutions of the monomers were 2%, 1% and 1% respectively, and had no effect on the divisions of the yeast cells, but they resulted in optimal concentrations for increasing the survival rate of the irradiated cells. A marked protective effect of these monomers against

TITLE: Auxiliaries to the IKS-14 spectrophotometer for investigating the spectra  
of very thin films

SOURCE: Pribory\* i tekhnika eksperimenta, no. 3, 1964, 142-145

TOPIC TAGS: spectrophotometer, IKS-14 spectrophotometer, infrared spectrum,  
photometric wedge

ABSTRACT: Auxiliary devices to the 2-beam IKS-14 spectrophotometer  
necessary for recording the infrared spectra of monomolecular films are briefly  
described. A multipass cell comprises two pairs of flat mirrors, each pair  
reflecting the beam 11 times; thus, the light passes the test film 22 times. The  
standard 4-tooth "comb" (photometric wedges) was replaced with a single wedge  
which increased the sensitivity to low optical densities fourfold. An experiment

Card 1/2

ACCESSION NR: AP4041037

corroborated the fact that the linear relation between the wedge travel and the transmission remained intact. A potentiometer bridge of 0.03% resolution was provided for extending the recorder scale. Records of NH<sub>3</sub> and Ca stearate spectra illustrate the gain in sensitivity. Orig. art. has: 4 figures.

TITLE: Analysis of radiation injury to deoxyribonucleoproteins at the molecular and  
supramolecular levels

SOURCE: AN SSSR. Izvestiya. Seriya biologicheskaya, no. 2, 1966, 197-210

TOPIC TAGS: radiation injury, protein, DNA, x ray irradiation, hydrogen bonding,  
molecular structure

ABSTRACT: X-irradiation does not give rise to covalent crosslinks within  
the DNA macromolecule, i.e., it does not prevent the separation of DNA  
strands or interfere with its replication. The authors' studies on optic  
rotation of DNA and DNP and melting curves indicate that irradiation causes  
latent damage to the system of hydrogen bonds. The formation of single  
breaks in the polynucleotide skeleton may result in rotation around the  
remaining single bond at the site of the break. This may produce local  
change in the configuration of the DNA macromolecule, resulting in steric  
hindrance between the DNA and corresponding protein molecule.

Irradiation with doses below  $10^5$  rad causes breaks only in a small  
number of DNA molecules. This does not alter the physicochemical properties  
of the DNA or DNP as a whole, although it undoubtedly has some biological

Card 1/2

UDC: 577.391

0579

0915

L 31194-66

ACC NR: AP6022568

effect. Thus, there is no reason to believe that the effects of low irradiation doses, as manifested in structural rearrangements of chromosomes, are related to changes in the DNA macromolecules. The results of studies on the physicomechanical properties of supramolecular oriented DNP structures present in a medium with physiological ionic strength indicate that these formations are highly sensitive to radiation. TITLE: A Conveyer With Hydraulic Drive (Konveyer s gidravlicheskim privodom)

PERIODICAL: Mashinostroitel', 1958, Nr 6, pp 14-15 (USSR)

ABSTRACT: In the Gor'kovskiy zavod frezernykh stankov (Gor'kiy Milling Machine Plant) a small car conveyer has been put into operation in the assembly of milling machines. The varicus parts needed for assembly are fastened on the cars which are moved by traction chains. The number of cars depends on the technological process and the number of parts needed. The conveyer is shown in figure 1. The hydraulic drive of the conveyer is represented in figure 2. Industrial oil type 20 is used in the drive, delivered by a pump with a productivity of 12 l/min, The pump is driven by an electromotor of 0.8 kw and 980 rpm. The speed of the conveyer is 30-40 mm/min. The hydraulic drive is used for assembly conveyers and washing machines.

AUTHORS: Gavrilyuk, A.M., and Gorin, A.M.

TITLE: Electrostatic Painting of Machine Parts

PERIODICAL: Mashinostroitel', 1959, Nr 7, pp 37-39 (USSR)

ABSTRACT: The article presents detailed engineering information on a special painting line for large-size machine parts, designed and used at the Gor'kovskiy zavod frezernykh stankov (Gor'kiy Milling Machine Plant). It is the first of its kind in the USSR. It consists of a painting and a drying chamber connected by an overhead suspension conveyer. In the painting chamber, the parts are moved between electrode gratings. The parts are under positive electric charge, and the paint sprayed by the six pneumatic sprayers at the output end of the chamber coats the parts with an even thin layer. To distribute the paint on the entire part, the parts are rotated at 6 rpm when they pass by the sprayers. The paint is fed from three pressure tanks with different colors of paint, and

Card 1/3

SOV/117-59-7-22/28

Electrostatic Painting of Machine Parts

the sprayers work in pairs, one pair for each color. The resetting of the spraying system for different shapes, or for different color, requires a few minutes; the height and the incline angle of the spray nozzles is easily adjustable on the posts with an incline scale (Figure 2). The drying chamber contains 160 special drying lamps for heating the parts to 110 to 120°C, placed on 16 movable shields permitting displacements within a 45° angle. The work of the ventilation system, the kenotron (rectifier), the sprayers, and the presence and the voltage of an electric field in the chamber is monitored by signal lamps on the control board. There is a special control, on the same board, for preventing the occurrence of sparks in the painting chamber. The equipment is grounded, and the installation need not to be stopped for charging parts on the conveyer or any resettings. The access doors to the chambers automatically block high voltage when opened. The

Card 2/3

SOV/117-59-7-22/28

Electrostatic Painting of Machine Parts

remaining electric charge is also automatically removed from the electrode gratings. The method is recommended for mass as well as small-lot and piece production of machines. It is mentioned that the Gor'kovskiy avtozavod (Gor'kiy Automobile Plant) was the first in the USSR to employ the method of painting in an electrostatic field. The article includes the technical characteristics of the installation and two illustrations. There are 2 diagrams.

PHYSICAL MEASUREMENT

SOV/2864

Gordin, Boris Mihailayevich and Nester Gavrilovich Lokshin

Tzmereniye ugla dielektricheskikh poter' pri nalichii vliyanii  
(Measurement of Dielectric Loss Angle in the Presence of  
Influencing Effects) Moscow, Gosenergoizdat, 1959. 55 p.  
(Series: Iz opyta sovetskoy energetiki) 4,300 copies printed.

Ed.: I. Ya. Yakobson; Tech. Ed.: G. Ye. Larionov.

PURPOSE: This booklet is intended for engineers and technicians  
employed in laboratories of electric power stations and substations.

COVERAGE: The authors discuss problems of measuring the dielectric  
loss-angle tangent in insulation in the presence of electric  
and magnetic fields. Methods of measuring the influence current  
and various methods of measuring  $\tan \delta$ , taking into account  
errors from the electric field, are discussed. Means of  
eliminating errors in the application of the method of phase  
adjustment and also formulas for reduced  $\tan \delta$  are presented.

Card 1/3

## Measurement of Dielectric (Cont.)

SOT/2864

The problem of the effect of the magnetic field on the accuracy of  $\tan \delta$  measurements is discussed and methods of measurement in the presence of electric and magnetic fields are given. No personalities are mentioned. There are 5 references, all Soviet.

## TABLE OF CONTENTS:

Introduction	5
Ch. I. Effect of the Electric Field	7
1. Statement of the problem	7
2. Influence current	8
3. Measuring the influence current	11
4. Errors caused by electric-field effects	15
5. Analysis of error formulas	19
6. Consequences of measuring $\tan \delta$ with errors	23
7. Methods of reducing error	25
8. Method of phase matching	27
9. Errors in measuring $\tan \delta$ using the phase-matching method	30
10. Method of successive approximations in measuring $\tan \delta$	32

Card 2/3

Measurement of Dielectric Losses

SOV/2864

11. Elimination of error in applying the phase-adjustment method and calculating according to the formula for reduced $\tan \delta$	36
Ch. II. Effect of the Magnetic Field	40
12. Statement of the problem	40
13. General considerations	41
14. Action of the influencing field on a bridge	42
15. Bridge equation under the influence of a magnetic field	44
16. Criterion for permissible degree of influence	45
17. Permissible degree of influence in two readings	49
Ch. III. Methods of Measuring $\tan \delta$ in the Presence of Influencing Factors	53
Bibliography	56
