described, the temperature of the source may be determined from the voltage ratio and the efficiency factor, from this temperature. The results obtained are in fair agreement with experimental data and with data in the literature. The same method can be used for determination of such other characteristics of the lamp as 1) the portion of energy focused on the sample and 2) the ratio of energy absorbed by the sample to that emitted by the lamp. It was determined that the former does not depend on voltage; its value for a small ruby, with an imperfect lighting system, was found to be 0.2%. The second parameter was slightly dependent on the voltage, and its value varied between 0.074 and 0.092%. The paper was presented by Academician B. I. Stepanov. Orig. art. has: 1 figure and 15 formulas.

SOURCE: Optika i spektroskopiya, v. 17, no. 1, 1964, 87-92

TOPIC TAGS: reflected radiation, transmission, scattering amplitude,  
optical absorption, optical transmission, luminor

ABSTRACT: In order to check on the validity of Bouguer's law in  
mediums in which the radiation density of a multiply scattered light  
is small compared with the intensity of the radiation itself, the  
authors calculated the attenuation of a parallel beam in a medium in  
which the absorption coefficient depends on the radiation intensity.  
The effect of various parameters (nonlinearity parameter, optical  
thickness, survival probability) on the transmission coefficient of

Card 1 1/5

ACCESSION NR: AP4042984

a plane-parallel layer is analyzed. A method is proposed to determine the nonlinearity parameter of the medium. The theoretical calculations are compared with experiments on organic phosphors with scattering inclusions. The nonlinearity parameter is determined for tripaflavine and acridine orange in sugar. The results agree within the limits of experimental error. "The authors are deeply grateful to L. Lukashenko for help in preparing many samples and in the measurements." TITLE: Diffuse reflection from optically thick layers of light-scattering media

SOURCE: AN SSSR. Izvestiya, Fizika atmosfery i okeana, v. 1, no. 6, 1965, 589-598

TOPIC TAGS: light reflection, light scattering, scattering glass

ABSTRACT: The authors discuss the results of an experimental investigation of diffuse reflection of light by scattering media of large optical thicknesses, with different values of the scattering indicatrix and different values of the probability of survival of a light quantum in the medium, and under different illumination conditions. The media employed were powders of various types of glass, concentrated emulsions, and suspensions (solutions in milk, rosin, polystyrene etc.). The procedures used for the various measurements were all

Card 1/2

L 2315-66

ACCESSION NR: AP5016287

3

described by various authors elsewhere, and references to these papers are given. The absolute coefficients of reflection were also investigated as functions of the same parameters. The experimental results agree well with various theoretical calculations made by different authors. The results show that the angular distribution of the reflected flux is affected little by the scattering indicatrix or by the quantum survival probability. As a rule, when the ratio of the reflected scattered light is large, the fraction of the light flux reflected in the specular direction relative to the incident beam is also larger, but even this effect is small. TITLE: Luminescence of a light-scattering layer with regard to transilluminance

SOURCE: Zhurnal prikladnoy spektroskopii, v. 3, no. 5, 1965, 421-427

TOPIC TAGS: luminescence, theoretical physics, light scattering, optic thickness

ABSTRACT: The authors calculate the radiative emittance of luminescence from a light-scattering layer with regard to transilluminance. An infinitely extended plane-parallel layer of a dispersive phosphor is considered. The following assumptions are made: this layer is illuminated on one side by a diffuse monochromatic radiation flux  $S_0$ ; diffraction and interference phenomena are insignificant; the excitation light and the light from luminescence due to multiple scattering are completely depolarized; the scattering particles are in a vacuum; the excitation light and the luminescence light are diffuse throughout the thickness of the layer. The authors analyze the effects which the various parameters of the light scattering layer and those of the excitation light have on the luminescence of the layer. Formulas are given for determining the upward and downward luminescence intensities. These formulas may be considerably simplified or approximated by analytical expressions in several cases of practical importance. The cases of excitation by weakly and strongly absorbed radia-

B

L 10894-66

ACC NR: AP6000023

tion, and luminescence from an infinitely thick layer are considered. It is found that although the technical luminescence yield is nearly independent of excitation power for an infinitely thick layer, there is a noticeable reduction in the technical luminescence yield with an increase in excitation power for optical thicknesses of the order of 1-10. AUTHOR: Ivanov, A. P.; Makarevich, S. A.

44155 44155

TITLE: The influence of optical characteristics on the spectral composition of radiation in turbid media

SOURCE: AN BSSR. Doklady, v. 9, no. 8, 1965, 504-508

TOPIC TAGS: solar radiation, solar radiation absorption, spectral absorptivity, photon, photon scattering, optic analysis, luminescence, water

ABSTRACT: It is known that the spectral composition of solar radiation penetrating aqueous media changes rapidly with depth. Using the theoretical investigations of V. A. Ambartsumyan (Izv. AN ArmSSR, No 1-2, 1944) as the starting point, the author investigates theoretically the spectral modification problem in details. Graphs and tables present 1) the spectral composition of the extinction coefficient  $\xi = \beta + k$ ; of the photon survival probability  $\Lambda = f / (\beta + k)$ ; of  $\beta$ ; of the transmission coefficient, of the primary light transmission coefficient, and of the luminosity; and 2) the luminosity magnitude as function of depth for various values of the parameter  $f$  describing ratio of the flux scattered forward (in the  $2\pi$  solid angle) to the flux scattered backwards by a unit layer. The paper concludes by a brief discussion concerning the measurability of the various parameters. Presented by Academician AN BSSR B.I. Stepanov. Orig. art. has: 5 formulas, 2 figures, and 1 table.

TITLE: Experimental study of some parameters in the theory of light scattering

SOURCE: Zhurnal prikladnoy spektroskopii, v. 2, no. 4, 1965, 356-362

TOPIC TAGS: light scattering, optic property, optic analysis

ABSTRACT: Parameters appear in G. V. Rozenberg's formula for a diffused radiation field which depend on the form of the dispersion coefficient  $\chi(\gamma)$ . Calculation of the parameters is complex and is carried out only in certain special cases. The physical meanings of these parameters are discussed, and experimental methods are proposed for determining them by measuring the photometric characteristics of radiation scattered by systems with particles of various optical properties in various binding media. Studies of the parameter  $g$  (having the physical meaning of brightness), optically transmitted in a diffuse manner by a thick layer of the medium, show that the angular distribution of the outgoing radiation is nearly independent of the survival possibility for light quanta within a wide range. Besides this,  $g$  is only slightly dependent on the form of the dispersion coefficient. Investigation of parameters  $h$  and  $S$  is based on measurement of the angular distribution of radiation diffusely reflected by

Effect of scattering on the intensity distribution in a turbid medium [Illumination by a narrow beam]

SOURCE: Optika i spektroskopiya, v. 18, no. 4, 1970, p. 705

PARTICULATE: turbidity, light scattering, milk, aerosol scattering, aerosol

ABSTRACT: An experimental analysis was made of the effect of the parameters of a source on the scattering of narrow light beams. The experimental setup consisted of a pulsed xenon lamp, a lens system, a highly turbid medium block, and a photographic system (camera). An optical system was used to introduce a narrow part of the beam from the pulsed xenon lamp into the turbid medium at the side. The camera was focused on the center. The illuminating system was kept open for a time interval of 100 microseconds. The photographic film was processed for 10 minutes.

parallel beam of light from a PRG-4 lamp into the tank from above or from below. The beam was subsequently scattered. The illuminating system was equipped to accommodate light filters, polaroids, and diaphragms. An RNU-25 photomultiplier was used to record the illumination in various parts of the medium. The photomultiplier, which was connected to the circuit of the experiment whose intensity was being measured, was located at a point within that segment by means of a light tube. The optical characteristics of the medium (natural indices of scattering  $\sigma$  and absorption  $\kappa$ ,

Card 1/2

were measured by means of an attachment to the SF-4 spectrophotometer, described earlier by the author (Jav. AN RSSP, Ser. Ciz, no. 2, 1962, 39). It was shown that the absorption coefficients are proportional with respect to the concentration of the solution. The absorption coefficient of the solution was determined from the absorption coefficient of a standard solution of the same composition. The absorption coefficient of the solution was determined from the absorption coefficient of a standard solution of the same composition. The absorption coefficient was determined from the absorption coefficient of a standard solution of the same composition. The absorption coefficient was determined from the absorption coefficient of a standard solution of the same composition.

the illumination at great depths and at short wave lengths and intensity (R) from the relation  
in which the narrow light beam is propagated. The formula, however, holds only  
for large values of the lifetime probability of a quantum. Practically speaking,  
the characteristics of a light field remain invariant to the degree of polarization  
for any specific absorption  $k/\sigma$ , a conclusion which is significant in the study of  
polarization phenomena and the theory of radiative transfer. Orig. art. has:

It was concluded that 1) for small optical thicknesses, the role of the solid angle subtended by the emitter is important since a slight decrease in the angular aper-		

perimentally the dependence of illumination on the angular aperture of the emitter. It was concluded that 1) for small optical thicknesses, the role of the solid angle subtended by the emitter is important since a slight decrease in the angular aperture leads to a sharp increase in the depth of penetration of light into the medium; 2) at given optical depths, depending both on the angular aperture and on the coefficient of scattering and absorption of the turbid medium, the relative change in the illumination, corresponding to different angular apertures, attains a maximum; and 3) for large optical thicknesses at different depths, the role of the angular structure of a narrow light beam incident on a medium remains unchanged--the angular aperture affects the illumination, but the

Card 1/2

L 54790-65

effect is minimal. It was also observed that the dependence of illumination on the angular aperture becomes more appreciable as the absorptive power is increased. Also, in highly absorbent media the illumination at large depths is more dependent on the illuminating conditions than in the weakly absorbent media. Orig. art. has 1 formula and 2 figures. [RE]

TITLE: Attenuation of a narrow parallel beam of light in a turbid medium

SOURCE: Zhurnal prikladnoy spektroskopii, v. 5, no. 2, 1966, 195-201

TOPIC TAGS: light beam, turbidity, turbid medium, light absorption, light attenuation, extinction coefficient, absorption coefficient, ILLUMINATION OPTICS, OPTIC DEPTH

ABSTRACT: The attenuation of a narrow beam of light in a turbid medium consisting of water in a tank, with optical density controlled by addition of milk or rosin, has been investigated. The absorptivity was varied by dissolving premeasured amounts of aniline black. A narrow collimated beam at  $\lambda = 546$  nm with a  $3.4\text{-cm}^2$  cross section and a divergence of  $1^\circ$  was produced by passing radiation from a DSh-250 lamp through a mercury filter. The results of the experiments were summarized in the form of graphs of the dependence of illumination on the optical depth at different values of the extinction coefficients ( $\epsilon$ ) and the dependence of illumination on the square of the extinction coefficient at different values of the optical depth ( $\tau$ ). It was shown that as a result of the negligible contribution of scattering, attenuation of light in slightly turbid media, in which  $\epsilon < 0.05 \text{ cm}^{-1}$  and  $\tau$  is less than 10, obeys the exponential law of absorption (Bouguer-Lambert

Card 1/2

UDC: 535.32/58

ACC NR: AP6030717

law). However, in media with larger coefficients of extinction, the exponential law of absorption is not obeyed at any depth, with the illumination at constant  $\tau$  increasing with the increasing coefficient of absorption. As  $\tau$  was increased at constant  $\Lambda = \sigma/(k + \sigma)$ , where  $k$  is the turbidity and  $\sigma$  is the absorption coefficient, the intensity of the scattered light was observed to increase, reach a peak, and then decrease to a limiting value equal to  $E/E_0$ , where  $E$  and  $E_0$  are the illumination inside and at the surface of the medium, respectively. As  $\epsilon$  increased the peak shifted toward larger  $\tau$ . The maximum illumination, which depends only on the scattered light, increases monotonically with  $\epsilon$ . The maximum illumination is sharper the smaller the value of  $\epsilon$ . Orig. art. has: 7 figures and 1 formula. [CS]

TITLE: Influence of the polarization properties of external radiation on the illumination of different sections of a turbid medium

SOURCE: AN BSSR. Doklady, v. 10, no. 1, 1966, 18-21

TOPIC TAGS: light polarization, radiation intensity, light scattering, light polarization, ILLUMINATION OPTICS

ABSTRACT: To check on a hypothesis that in a strongly turbid medium the orientation of the intensity vector of the external radiation would be less important than in a weakly turbid medium, and to obtain quantitative estimates of this difference, the authors have experimented with the influence of the electric-intensity vector orientation on the illumination produced by radiation in a light-scattering medium. The investigations were carried out with apparatus described earlier (Opt. i spektr. v. 18, no. 4, 1965). The polarization plane was rotated with the aid of a polaroid. The theory of the experiment is briefly described. The tests were made with the optical receiver immersed in the turbid medium to different depths. Plots are presented of the percentage change of electric intensity against the orientation of the electric vector and against the extinction coefficient. The results show that the larger the extinction coefficient, the smaller the influence of the polarization angle on the

Card 1/2

L 37090-66

ACC NR: AP601759<sup>4</sup>

O

intensity. The plots of the change of intensity against the polarization angle are symmetrical about the value at 90°, at which their relative change of intensity has a maximum. It is concluded from the results that at large distances from the point of penetration of the light into the medium, or in the case of strong turbidity, differences in the orientation of the electric intensity vector of the incident radiation do not change the illumination noticeably. However, when the turbidity is low and the multiple scattering is small, the illumination may change by a factor of two as the angle of polarization changes from 0 to 90°. This report was presented by AN BSSR Academician B. I. Stepanov. Orig. art. has: 2 figures.

TITLE: Effect of the angular dispersion of a light beam on its penetration into a scattering medium

SOURCE: AN SSSR. Izvestiya. Fizika atmosfery i okeana, v. 2, no. 3, 1966, 312-315

TOPIC TAGS: optic property, ocean property, oceanography, light dispersion, light scattering, water

ABSTRACT: The problem of the effect of the angular dispersion of a light beam on illumination in a turbid medium was investigated experimentally. The experiments were set up in a small basin filled with turbid water. The method of investigation was such that it was possible to change both the angular aperture of the radiator from 0.5 to 180° at a constant luminous flux entering the water and the optical characteristics of the medium, the probability of photon survival, and the optical depth. The cross sectional area of the light beam entering the water was 3.14 cm<sup>2</sup>. The authors examined the region of small optical depth which corresponds to a slightly turbid atmosphere, space, and water to shallow depths; the region of average optical

Card 1/2

UDC: 551.593

L 40931-66

ACC NR: AP6011374

depths; and the region of large optical depths. It is concluded that the greater the probability of photon survival, the slower the illumination decreases with an increase of the radiator aperture angle. At large optical depths illumination depends on the angular dimensions of the radiator but not as much as could be expected. Illumination drops not by several orders of magnitude but only by a factor of 2-3 when an acutely directed radiator is replaced by a completely diffusive one. Orig. art. has: 4 figures and 2 formulas.

Text: Reported the expediency of using Tm<sup>170</sup> for examination of welded and cast articles from steel and light alloys. Operating characteristics for running of the industrial pilot plant for ГУП-Ty 0.5-1 (GUP-Tu-0.5-1) were determined and its construction faults have been determined as well as economic efficiency of gamma-ray testing of large welded constructions. The sources with an activity of 0.5 gr eq. of radium can be widely used in gamma-ray testing, provided the output is not the essential factor, but sources of smaller activity are required for protective shielding and transport.

TOPIC TAGS: asbestos product, synthetic fiber, fluoroamphibole fiber, heat resistance, tensile strength

ABSTRACT: The relative tensile strength at room temperature has been determined in fibers of synthetic lithium-magnesium fluoroamphibole  $\text{Li}_2\text{Mg}_6[\text{Si}_8\text{O}_{22}]F_2$ , synthetic fluorricherite  $\text{Na}_2\text{Mg}_6[\text{Si}_8\text{O}_{22}]F_2$ , and natural crocidolite asbestos which were heat-treated at a temperature in the 200-800°C range. These determinations were necessary to supply data on the effect of heat treatment on mechanical properties of the fibers which are important for high temperature technology because of their high heat resistance. All data in this study were related to the fibers of 1.5 μ in diameter.

Isomerization of methylphenylacetylcarbinal in acid medium. E. D. Venus-Danilova, A. P. Ivanov, and I. I. Martynov (Leningrad Technol. Inst., Leningrad). Zhar. Obshch. Khim. (J. Gen. Chem.) 21, 1800-10 (1951).-- Treatment of  $(Br_2C_6H_5)_2CHCOCl$  with PhAc and EtOH in Et<sub>2</sub>O gave 31%  $MePhCO(OH)ClCH$  (I), m. 48.5-9.5°; purification is best done by steam distn. of the petr. ether ext. of the reaction mixt. after hydrolysis. A 36-42% yield of corresponding diol is also obtained. I (4 g.) in 20 ml. 60% AcOH and 3.5 g. Hg(OAc)<sub>2</sub> in 30 ml. 60% AcOH kept 2 hrs. on a steam bath, gave 2.2 g. unchanged I and a trace of a reducing substance. However, 4 g. I in 20 ml. EtOH, 2 g. HgO, and 100 ml. 1:7 H<sub>2</sub>SO<sub>4</sub> kept 3 hrs. on a steam bath gave from several runs an av. yield of 22.8% methylphenylacetylcarbinal (3-hydroxy-3-phenyl-2-butanone), b.p. 80-81° (semicarbazone, m. 182-3°), and 14.8%  $MePhC_6H_4CHO$ , b.p. 70-7° (semicarbazone, m. 100-0°); the best sepa. is via the semicarbazone route. Oxidation of the aldehyde by Ag<sub>2</sub>O failed, yielding only AcPh. The aldehyde probably forms by anionotropic rearrangement of the acetylene-alene type through the enolic form of the aldehyde. O. M. Kosolapoff

Addition of hydrogen to acetylenic derivatives. III (2). Catalytic hydrogenation of phenylated butyndiols in the presence of colloidal palladium. Yu. S. Zal'kind and A. P. Ivannov. *J. Gen. Chem. (U. S. S. R.)* 11, 861-864 (1931); cf. C. A., 35, 6360g. The authors made a comparative study of the hydrogenation of 10 acetylenic diols in the presence of colloidal Pd under controlled conditions.  $\text{EtMgBr}$  (from 30 g. Mg) was treated, with cooling and stirring, with 0.5 g.  $\text{McCOPh}$  and 18 g. abs.  $\text{EtOH}$  in dry  $\text{EtO}_2$ , let stand 24 hrs., treated with moist  $\text{Et}_2\text{O}$ , the aq. layer treated with weak  $\text{H}_2\text{SO}_4$ , and  $\text{Et}_2\text{O}$ ; both exts. were dried and the  $\text{Et}_2\text{O}$  distilled; the 1st ext. yielded a mixt. of *cis*-dimethylphenylbutyndiol and 2-phenyl-3-butyn-2-ol (I); the latter was dissolved in warm petr. ether, the solvent distilled, and the residue steam-distilled, the distillate satd. with  $\text{K}_2\text{CO}_3$  and extd. with  $\text{Et}_2\text{O}$ . The 2nd  $\text{Et}_2\text{O}$  ext. treated as above also yielded I, giving a total of 21.5 g. I (20.4%), m. 105.0° (from petr. ether).  $\text{EtMgBr}$  (from 14.4 g. Mg) in ether was treated with 21 g. dimethylethyndiol in  $\text{EtO}_2$  with cooling and stirring, followed by 24 g.  $\text{Et}_2\text{O}$  in ether, after 2 days the mixt. was treated with moist  $\text{Et}_2\text{O}$  and ice water, and the aq. layer treated with dil.  $\text{H}_2\text{SO}_4$  and extd. with  $\text{Et}_2\text{O}$ . On distn. of the  $\text{Et}_2\text{O}$  both exts. gave crystals of 4-methyl-1-phenyl-2-pentyn-1,4-diol (III), which was recrystd. from benzene and  $\text{EtOH}$ ; 20 g. (46.4%), m. 73.5-74°.  $\text{EtMgBr}$  (from 3.0 g. Mg), treated with 0.9 g. phenylethyndiol in ether, cooling and stirring, warmed for 0.5 hr. on a water bath, then treated with 0.4 g.  $\text{Ph}_2\text{CO}$  in ether and let stand for 3 days, heated for 0.5 hr. on a steam bath and worked up. m. 105.0°.

## METALLURGICAL LITERATURE CLASSIFICATION

above, gave 11 g. (67.8%) 1,1,4-triphenyl-2-butyne-1,4-diol (III). III was also prep'd. from  $\text{EtMgBr}$  (from 2.5 g. Mg), 10.4 g. diphenylethyndiol and 3 g.  $\text{Et}_2\text{O}$  in 94.2% yield. III, m. 110-111°. 2-Methyl-3-phenyl-3-hexyne-2,5-diol (IV), prep'd. as described above from 11.4 g. Mg, 60 g.  $\text{Et}_2\text{O}$ , 24 g. dimethylethyndiol and 27 g.  $\text{McCOPh}$ , in 70.2% yield (35 g.), m. 81.5-82°. 1,1,4-Triphenyl-2-pentyn-1,4-diol (V), prep'd. as described above from 4.8 g. Mg, 22 g.  $\text{Et}_2\text{O}$ , 14.6 g. I, and 15 g.  $\text{Ph}_2\text{CO}$ , in 34.6% yield (6.4 g.), m. 123.5-124°. 3-Methyl-1-(9-hydroxy-9-fluorenyl)-1-butyn-3-ol (VI), prep'd. from 37 g. fluorenol, 18 g. Mg, 88 g.  $\text{Et}_2\text{O}$  and 31 g. dimethylethyndiol as described above, was obtained in 62.7% yield (34 g.), m. 161.5-162° (from  $\text{EtOH}$ ). The 5 glycols and 6 previously known ones: diphenyl-, tetra-

methyl-, *cis*-dimethylbiphenyl-, *cis*-dimethoxyphenyl-, and tetraphenylmethanol, were hydrogenated alike, by using 0.01 mol. of the glycol in 50 cc.  $\text{Et}_2\text{O}$  and 2 mg. colloidal Pd. All but V and tetraphenylmethanol were run at 19° and 748 mm.; the remaining 2 were run at 17.6° and 748 mm., and 20° and 758.5 mm., resp. In addn., extns. were also run with 4 mg. Pd catalyst, and all new glycols (II-VI) were also run with 8 mg. Pd. The reaction consts. ( $\times 10^3$ ) for 2 mg. Pd were found to be: diphenylbutyndiol 9.6, II 6.10, III 3.3, tetramethyl-

butynediol 3,6, IV 3,6, *oxym-dimethylidiphenylbutynediol* 3,4, *xylo-dimethylidiphenylbutynediol* 1,37, V 0.80, *tetraphenylbutynediol* 0.43, VI 4.00. For 4 mg. Pd, the values were: 13.2, 11.2, 7.00, 10.1, 10.4, 8.6, 1.2, 2.1, 0.94 and 11.3, resp. Hydrogenation with 0 mg. Pd was run mainly to observe any rapid change of rate of hydrogenation after addn. of the 1st 2 H atoms; in all cases a definite decrease of hydrogenation rate was observed after formation of the ethylene glycol-type structure. Although the reaction, in general, is not strictly a 1st-order reaction, and  $K$  varies in the course of its progress, the av. values of  $K$  (given above) were calc'd. because they are convenient measuring comparison standards. The products of hydrogenation of II-VI were isolated as follows: the Pd was filtered off, the  $\text{Et}_2\text{O}$  distil. in vacuo, the residue dissolved in  $\text{Et}_2\text{O}$ , dried, the  $\text{Et}_2\text{O}$  distil. off and the residue distil. if possible. II yielded *4-methyl-1-phenyl-2-pentene-1,4-diol*, m.p. 154.0°; III yielded *1,1,4-triphenyl-2-butene-1,4-diol*, a viscous liquid which could not be distil. without decompr.; IV yielded *2-methyl-3-phenyl-3-hexene-2,5-diol*, b.p. 173-87°; V yielded *1,1,4-triphenyl-2-pentene-1,4-diol*, m.p. 75.0° (from benzene); VI gave *3-methyl-1-(9-hydroxy-9-fluorenyl)-1-buten-3-ol*, m.p. 142.3° (from  $\text{EtOAc}$ ). In general, disubaryl and secondary tertiary glycols hydrogenate more readily than do the tertiary glycols of comparable mol. wt. Substitution of Ph groups for Me groups leads to a slower hydrogenation rate. Closure of 2 Ph groups into a fluorene nucleus causes a great increase in hydrogenation rate, showing the effect of steric structure of the mol.

TITLE: Determination of the extinction coefficient of turbid media

SOURCE: AN SSSR. Izvestiya. Fizika atmosfery i okeana, v. 2, no. 7, 1966, 721-728

TOPIC TAGS: turbid medium, light scattering, light reflection coefficient

ABSTRACT: This article examines the problem of the effect of scattered light on the effective magnitude of the extinction coefficient as a function of the optical parameters of the medium and angular characteristics of the source and receiver. Tables of errors in the measured values of the extinction coefficient are presented and, by using the data of these tables, it is possible to make recommendations concerning the choice of the measurement instrument under certain conditions when a given accuracy of measurement is required. Milk, an alcoholic solution of rosin, and a solution of polystyrene in acetone diluted with distilled water were used as media having different scattering indicatrices. Bouguer's law was used to determine the extinction coefficient. It was found that the error in determining the extinction coefficient for a milk medium was highest owing to the greater elongation of the indicatrix of refrac-

TITLE: Mechanical properties of synthetic fibrous fluor-amphiboles and certain  
natural asbestoses

SOURCE: AN SSSR. Izvestiya. Neorganicheskiye materialy, v. 1, no. 7, 1965,  
1221-1228

TOPIC TAGS: asbestos, fluoride mineral, fiber crystal

ABSTRACT: Mechanical properties of crocidolite asbestos from an African deposit, anthophyllite asbestos from the Sysert' deposit, chrysotile asbestos from the Bazhenovo deposit, and two types of synthetic fibrous fluor-amphiboles (lithium fluor-amphibole and magnesium fluor-richterite) were investigated. Values of the tensile strength and stress-strain diagrams for fibers of various diameters were obtained for each material. From these diagrams, a qualitative estimate of Young's modulus in the direction of the tension is made. Analytical relations are derived which permit the calculation of the strength of fibers of various diameters. It is found that several mechanical properties of natural asbestoses and synthetic fluor-amphiboles (high tensile strength, dependence of

strength on diameter) are identical to the properties of filamentary crystals (whiskers). Certain differences in the mechanical properties of the fibers of these materials are apparently due to structural differences. A possible mechanism of the rupture of fibers of natural asbestos and synthetic fluor-amphiboles is discussed. "The authors thank A. V. Stepanov, Doctor of Mathematical Sciences, and A. D. Fedoseyev, Doctor of Technical Sciences, for their joint review of the results."
