TITLE: Contribution to the Study of Surface Tension on the  
Austenite Grain Boundaries <sup>10</sup>

PERIODICAL: Hutnické listy, 1961, No.1, pp.41-49

TEXT: The surface energies of melts have been measured by numerous authors and adequate data are available. However, few measurements have been made of the surface tension of solid substances or at the grain boundaries. For steel, only the data published by Van Vlack (Ref.2) on the absolute values of the surface tension at the austenite grain boundaries are available. The views of Read and Shockley (Ref.3) on the properties of grain boundaries have been experimentally verified as a function of the grain orientation by a number of authors, for instance Dunn, Daniels and Bolton (Ref.4) and Aust and Chalmers (Ref.5). So far, no work has been published in Czechoslovakia on measuring the relative and absolute surface tension at the grain boundaries of steel. In this paper the results are published of measurements of the relative energy at the grain boundaries of two different phases (ferrite and

Contribution to the Study of Surface Tension on the Austenite Grain Boundaries

austenite) and on the austenite grain boundaries. In the final part of the paper an attempt is made to determine the absolute surface tension of austenite by means of a modification of the Sears method (Ref.7). The relative values of the surface tension at the austenite-ferrite grain boundary for the isothermal decomposition temperature of 750°C, determined by means of statistical evaluation of the angles between individual grains measured in the plane of the polished section, were found to be:  $\sigma_{\alpha\gamma} \approx 0.7 \sigma_{\gamma\gamma}$  and  $\sigma_{\alpha\alpha} \approx 0.9 \sigma_{\gamma\gamma}$ . For the interphase δ-ferrite-austenite, the following relations were found to apply for the temperature range 1000 to 1200°C:  $\sigma_{\delta\gamma} \approx 0.83 \sigma_{\gamma\gamma}$  and  $\sigma_{\gamma\gamma} \approx 1.2$  to  $1.4 \sigma_{\delta\delta}$ . Further statistical data were obtained and a critical analysis was made of the applied method of measuring the relative surface tension between two phases. The theoretical frequency curve for angles of 85° between grains was determined and this curve is compared with experimentally determined curves of frequencies with a modal value

Card 2/5

Z/034/61/000/001/007/021  
E073/E535

Contribution to the Study of Surface Tension on the Austenite Grain Boundaries

of  $\theta = 85^\circ$ . The two curves were found to be in good agreement; the modal value of the angle determined experimentally is in agreement with the real angle between the two grains investigated. By means of vacuum etching of the surface of specimens, a method was developed of measuring the relative surface energy  $\sigma_{hr}$  between the austenite grains. The specimens were etched in the temperature range 1050 to 1100°C for durations of 48 hours, maintaining the vacuum at  $3 \text{ to } 5 \times 10^{-4} \text{ mm Hg}$  col. Furthermore, a method was developed for measuring the angles of "wrinkles" by the type MIS-11 profile meter and an evaluation was made of some of the data on a method of measurement and the shape of the wrinkles which form during vacuum etching. For soft carbon steel and two alloy steels (with 1% Cr and with 1% Cr + 1% Ni), the relative value  $\sigma_{hr} = 0.6$  to 0.75  $\sigma_v$ , which corresponds to an average value of the wrinkle angles of  $\theta = 136$  to  $145^\circ$ . By means of the modified drop method, the absolute surface tension on the free austenite surface was determined, using spectrally pure lead as a standard material. The

Contribution to the Study of Surface Tension on the Austenite  
Grain Boundaries

experiments were carried out in a carefully purified atmosphere of argon and unsaturated lead vapours at 900°C for a duration of 4 hours. On the basis of the equilibrium of the surface tension vectors in the horizontal and vertical directions, the surface tension was determined under the above given conditions for two types of steel; for the soft carbon steel  $\sigma = 1240$  dyn/cm and for the 30ChN2MA steel  $\sigma = 1300$  dyn/cm. Furthermore, an analysis was made of the shape of the lead drops as determined in the transverse cross-section on the surface of the specimen during measurement of the  $\sigma$  values. Finally, the absolute surface tension at the grain boundaries on eliminating the influence of unsaturated lead vapours was tentatively calculated. The surface tension at the austenite grain boundaries at 1100°C was found to be about 800 dyn/cm for soft carbon steels. In evaluating the influence of lead vapours on the wrinkle angles, it was found that this influence is small and in the given case brings about a change of the wrinkle angles from 144.5 to 139°. So far, this quantity

has not been measured on other alloys investigated but work on this point is continuing. Some of the measurements were carried out by Engineer Kašik, VUHZ, Prague. There are 19 figures and 28 references: 5 Czech, 1 Soviet, 1 French, 1 German and 20 English.

TITLE: Study of the influence of oxygen on surface tension

PERIODICAL: Hutnické listy, 1961, No.8, pp.561-565

TEXT: A number of authors have expressed the view that an increased content of oxygen produced intergranular brittleness in steel. J.Plateau, G.Henry and C.Crussard (Ref.2: Precipitation Processes in Steels; Iron and Steel Inst. Spec. Rep. No.64, 1959, pp.157-176) have pointed out that a relation may exist between intergranular brittleness and segregation of oxygen at the grain boundaries. In this paper, the authors investigate other causes of this brittleness. An attempt is made to determine more accurately the crystallographic relations pertaining to stripes on free surfaces, revealed after high-temperature etching at low pressures. Furthermore, certain views are expressed on the properties of fractures, since similar stripes were observed on fracture surfaces, particularly in cases of braked fractures in martensite when the fracture was

mostly along the grain boundaries. Under such conditions, the formation of stripes has not hitherto been observed. J.Bénard, J.Moreau and J.Plateau (Ref.6: Zeitsch. Electrochemie, 61, 1957, pp.59-65) explain the stripe formation by the fact that adsorption of oxygen reduces the surface energy, particularly on some crystallographic planes. This facilitates changes on the surface of the specimen caused by surface diffusion, enabling formation of non-uniformities corresponding to those planes where the surface energy is lowest. A certain analogy can be anticipated between the character of these striped surfaces and certain fracture surfaces which occur during intercrystalline fractures. In the case of grain boundaries, the probable cause of formation of stripes are oxygen atoms which are dissolved in the metal and can be adsorbed at the grain boundaries. The experiments were made on the steel 30ChN2MA produced in a 40 kg high-frequency laboratory furnace in such a way as to obtain an increased oxygen content (0.016%). After forging, the material was homogenized at 1000°C for one week. From this material, specimens were produced for studying the mutual orientations of the stripes and the crystallographic planes. After careful

Study of the influence of ...

preparation of the surface of the polished specimens, these were vacuum-etched at  $1050^{\circ}\text{C}$  at a residual pressure of  $3 \times 10^{-3}$  to  $1 \times 10^{-3}$  mm Hg for durations of 2 - 48 hours. Under such conditions, no continuous oxygen layers formed on the specimens and oxygen was only adsorbed at the surface of the material. For comparison, the stripe-formation was also investigated after studying braked fractures. These test specimens were austenitized at  $1100^{\circ}\text{C}$  for 1 hour and then water-quenched. After quenching, the specimens were loaded for 1 hour with a static stress of  $60 \text{ kg/mm}^2$ , corresponding approximately to  $0.35 \sigma_p$  of the given steel after quenching. The braked fractures occurred after the load has been applied for 30 to 50 minutes. It was found that the stripes on the free surface were parallel to the planes {111} or {100}. The preferential etching of the plane {100} indicates that the adsorbed oxygen reduces the surface tension in this plane much more intensively than in the planes {111} which should have the lowest surface energy, since they have the densest atom population. The striping is attributed to a decrease in the surface energy. The gained energy forms the motive force of surface diffusion on the

Study of the influence of ...

grain boundaries and brings about stripe formation at spots which are suitably oriented. It was found that a close relation exists between stripe-formation on the free surface and on fractures. An explanation is given why stripe formation is difficult to observe on fractures; it was observed for the first time on quenched steel during tests involving braked fractures and on soft carbon steels. J.Plateau et al (Ref.2) were not successful in detecting stripe formation in the Fe-O system by means of optical fractography. A direct relation exists between the adsorbed oxygen, the stripe-formation and the strength properties of the steel. In accordance with the theory of Griffith, a drop in the surface energy in the presence of adsorbed oxygen on the grain boundaries leads to a decrease in the critical size of cracks in intercrystalline fractures, i.e. to easier fracture. TITLE: On the resistance limit and the mechanism of failure of the metal ceramic solid alloy of WC and Co at compression

SOURCE: Fizika metallov i metallovedeniye, v. 17, no. 4, 1964, 572-577

TOPIC TAGS: resistance limit, yield stress, stress analysis, cobalt, carbide phase, dislocation effect, tungsten carbide

ABSTRACT: The purpose of this work was to obtain systematic experimental data on the effects of composition and carbide grain size on the resistance limit of the alloy WC-Co during compression. Five sets of alloys were prepared with varying sizes of carbide grains (1.4, 1.7, 1.9, 3.3, and 5.3  $\mu$ ). In each set specimens were prepared containing varying percentages of cobalt. The different grain sizes were obtained by changing the initial temperature at which the powder was formed. The results showed that (with increasing cobalt content) the resistance limit increased initially and then decreased monotonically; all the curves reached a

APPROVED FOR RELEASE: 08/10/2001

CIA-RDP86-00513R000620310001-8

size of 1.4-1.7  $\mu$  was attained for 5% by wt (8.6% by vol) of cobalt in the alloy.

Card 1/3

ACCESSION NR: APL034055

The resistance limit is given by the theoretical expression

$$\sigma(S_T) = \frac{A}{v^{1/4}} + B;$$

$$\sigma(S_T) = \frac{C}{v^{1/4}} + D,$$

where  $\sigma$  is the resistance limit,  $S_T$  the yield limit,  $v$  the volumetric content of Co, and A,B,C,D are constants. The theoretical dependence of the resistance limit on the grain size is given by

$$\sigma_c = \frac{a}{d} + B';$$

$$\sigma_c = \frac{b}{d^{1/4}} + D',$$

where d is the grain size and a,b,B'D' are constants. The form of the experimental curves agrees with these expressions. Finally, it was shown that these dependences were adequately described by the dislocation theory of E. Orowan (Symposium on Internal Stresses in Metals and Alloys, Inst. Metals, London, 1948) and of F. V. Lenel and G. S. Ansell (Powder Metallurgy. Proc. intern. Conference held in N.J., June 13-17, 1960, p.267). Orig. art. has: 7 formulas, 3 figures, and 1 table.

**Notes:** This book is intended for structural, exploration and mining geologists.

and industrial planners.

**CONTENTS:** This work purports to be the first attempt to review and summarize all the material which has been published on the ironore deposits of the Altay-Sayanobaychik district during the last 20 years. This area, the work reports, is fast becoming one of the most important iron-ore bases in the Soviet Union. The book discusses the economic aspects of the geography and geology of the individual deposits, presents a qualitative and quantitative (as of January 1, 1977) analysis of ore reserves, and estimates the prospects and possibilities of further development of the Altay-Sayanobaychik iron-ore base. The genetic characteristics of iron-ore mineralization of the area are described. Descriptive information on the geology of individual deposits, complexes, and regions is presented, and a general genetic description of ore mineralization is also given. There is a section on the history of the development of the exploration and development of the region, and of the development of concepts on the genesis of mineralization in the area. The following scientists participated in the preparation and writing of this volume: G.D. Popov, N.S. Laptin, N.N. Slobodan, V.M. Chervotkin, O.G. Klim, and V.A. Volkov, members of the West Siberian Branch of the AS SSSR; I.D. Shadrin, member of the Permanent Interdepartmental Committee on Iron, A.B. Fal'chev, A.B. Mednik, I.A. Gorshkov, A.B. A. 			Titanium carbide	Tantalum carbide	Tungsten carbide	Cobalt
TT7K12	13.1	87-88	4	3	81	12
TT7K15	12.7-13.0	87-88	4	3	78	15
T5K12V	12.9-13.0	67-88	5	-	83	12

Cutting tests were conducted at the Uralmashzavod, Kolomenskiy teplovozostroitel'nyy zavod (Kolonna Diesel Locomotive Plant), Stankostroitel'nyy zavod im. Ordzhonikidze (Machine Tool Plant im. Ordzhonikidze), LIL, GAZ, Kramatorskiy zavod tyazhelogo mashinostroyeniya (Kramatorsk Heavy Machinery Plant), and the Elektrostal'skiy zavod tyazhelogo mashinostroyeniya (Electrostal' Heavy Machinery Plant). The results show that TT7K15 has the highest strength but only half the durability of TT7K12, and the T5K12V has almost the same cutting properties as

The cutting properties .....

TTKL2 but lower wear resistance. Generally, the strength of the new alloys in cutting is considerably higher than that of the standard carbides T5K10 (T5K10), BK8 (VK8) or BK11 (VK11) in cutting with deep cut. They proved good in heavy and intermittent cutting with relatively high cutting speed, and they are initially being used for planing large machine parts at the Kolomna Diesel Locomotive Plant, etc., as well as for planing large steel plates for dies at the Gor'kovskiy avtomobil'nyy zavod (Gor'kiy automobile Plant). The following conclusions are clear: (1) TT7KL2 and T5KL2V alloys are basically used as substitutes for high-speed steel in rough turning, turning on welds, planing, and other machining where the strength of standard carbides is not sufficient for dependable tool performance. In rough turning, they often can replace the T5K10 alloy, and the feed rate then be raised 1.5 times or doubled, and the cutting speed slightly reduced. (2) The strength of TT7KL2 and T5KL2V is mostly sufficient; since the TT7KL5 alloy is strong and has a lower wear resistance, it would be better to use it only in individual cases. (3) The use of the new alloy will have negative results in cases where the T5K10 alloy works without too much crumbling of the cutting edge and where any considerable increase in the cut depth is technically impossible or

The cutting properties .....

inexpensive. (4) The cutting capacity of the TT7K12 and TSK12V alloys is much higher than that of high-speed steel when the cut is deep, but the difference abruptly diminishes or even disappears in operation with low feed (of about 0.1 mm/rev). More experiments are necessary before it can be seen whether the new alloys ought to be used for shallow cutting. (5) In future, it is necessary to investigate whether the new alloys should be used for cutoff tools and complex-shaped cutters, to determine the effect of cutting tips of the new alloys on tools for materials difficult to cut, and to achieve stable cutting properties for the TT7K12 and TSK12V alloys. There are 3 tables and 5 figures.

Abstract : A study was made of water-free, generator shale tar, deprived of polar and high-molecular compounds, of two of its fractions, boiling range up to 200° and 200-300°, and of the gas gasoline produced by gasification of the shale; the products under study were subjected to

TITLE: Solvable Lie Standard Algebras.I

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Matematika, 1959,  
Nr 6, pp 58-71 (USSR)

ABSTRACT: A zero algebra is called complete if its orthogonal complement is its normalizer. According to G.B.Gurevich [Ref 2] a linear Lie algebra is called a Lie standard algebra if its normalizer is identical with the normalizer of a complete zero algebra. In the present paper the author determines the center  $Z_B$ , the commutant  $[B^2]$  and the differentiation algebra  $A_B$  for an arbitrary solvable Lie standard algebra  $B$  being no zero algebra. Under consideration of numerous single cases the results are formulated in three theorems.  
There are 5 Soviet references.

TITLE: A Method for Determining the Lower Border Altitude of  
Intramass Stratified Clouds (O metode opredeleniya  
vysoty nizhney granitsy vnutrimassovykh sloistykh  
oblakov)

PERIODICAL: Tr. Leningr. gidrometeorol. in-ta, 1956, Nrs 5-6,  
pp 201-207

ABSTRACT: The authors examine the position of the condensation  
level in light of the proposition that heat and moisture  
transfer is brought about not only by vertical move-  
ment but also by turbulent exchange. Using the  
equations for water vapor transfer and for heat ab-  
sorption by dry air, they derived an equation for the  
transfer of humidity deficiency. The equation for

Card 1/3

14-57-7-14642

A Method for Determining the Lower Border (Cont.)

the altitude of condensation level is first derived, with the element of turbulent exchange left out of the calculations; it is noted that, under this condition, the equation gives low altitude values, because turbulent exchange equalizes the moisture deficiency and raises the altitude at which the deficiency becomes zero. The authors also derive an equation for the altitude of condensation level, taking the turbulent exchange into account. The results of their calculations are represented graphically. The altitude of condensation level is determined from the amount of relative humidity, the temperature at the earth's surface  $T_0$ , and the magnitude of  $\alpha/D$ , where

$$\alpha = \frac{\gamma - g/R}{L/AR_w T - 1} + \gamma_a,$$

Here  $\gamma$  is the vertical temperature gradient,  $\gamma_a$  is the adiabatic gradient,  $g$  is acceleration of gravity,  $R$  and  $R_w$  are constants  
Card 2/3

A Method for Determining the Lower Border (Cont.)

14-57-7-14642

for air and water vapor, A is the thermal equivalent of the work, T is temperature at the condensation level, and D is the coefficient of turbulent exchange. When the value of  $T_0$  is constant, the altitude H of condensation level is determined by the equation

$$H/(l-r) = f (\alpha/D).$$

The condensation level rises as the value of  $T_0$  increases, and falls as the temperature gradient increases.

Kamenskaya, S. A.

TITLE: Mastication of Natural Rubber in the Presence of Para-Tertiary Butylphenolmercaptane, Dimethylphenylparacresolmercaptane, Their Zinc Salts and Disulfides

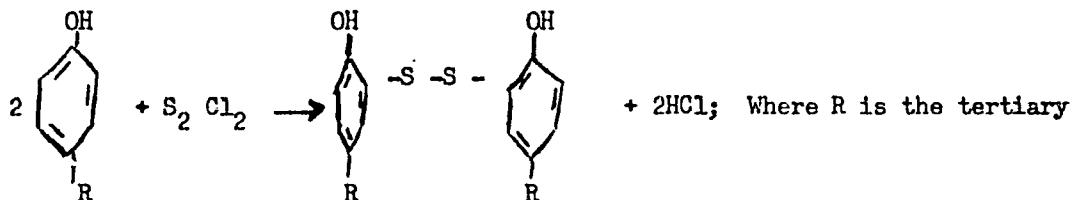

PERIODICAL: Kauchuk i rezina, 1960, No. 11, pp. 21-24

TEXT: The results are given of work carried out on the synthesis and study of paratertiary butylphenolmercaptane, dimethylphenylparacresolmercaptane, their zinc salts and disulfides, as accelerators of natural rubber mastication. The method for producing the listed accelerators is outlined and a characteristic evaluation of these is given. Corresponding disulfides were used as the initial products for producing substituted arylmercaptanes. Both products under investigation were obtained by reacting sulfur monochloride with paratertiary butylphenol and dimethylphenylparacresol. The reaction is given as:

Card 1/5

butyl- or dimethylbenzyl. The reaction was carried out in a solution of dichloroethane at its boiling point. Sulfur monochloride was added gradually, mixing for 2 hours. At the end of the reaction the dichloroethane was distilled off and the product obtained dried in a vacuum at a temperature of 40-50°C until a constant weight was achieved. The disulfide yields were 82 and 87% of the theoretical, respectively. The obtained products, which were resin-like substances, were subjected to an elementary analysis. The results were: for

The results showed that the synthesized substances correspond to disulfide of paratertiary butylphenol and disulfide dimethylphenylparacresol. In order to obtain corresponding mercaptanes from the disulfides the reduction method was used with glucose and alkali hydroxide in an alcohol-aqueous medium (Ref. 3). Results of an analysis of the zinc content in the zinc salt of the corresponding mercaptane proved that sodium mercaptide and not phenolate is formed when reducing the disulfides with glucose and a calculated quantity of alkali hydroxide. The mercaptane yield was 90 and

Mastication of Natural Rubber in the Presence of Para-Tertiary Butylphenolmercaptane, Dimethylphenylparacresolmercaptane, Their Zinc Salts and Disulfides

97% of the theoretical, respectively. Zinc salts of the paratertiary butylphenolmercaptane and dimethylphenylparacresolmercaptane were obtained from the respective sodium mercaptides formed in the process of the disulfide reduction. The yield of the commercial product was 96% of the theoretical. The zinc content for the  $C_{20}H_{26}O_2S_2Zn$  was calculated to be 15.2% and found experimentally as 14.7%. The authors point out that they were first to obtain the mercaptanes of the paratertiary butylphenol and dimethylphenylparacresol, their zinc salts and also dimethylphenylparacresol disulfide. A study was carried out of the action of the paratertiary butylphenolmercaptane, dimethylphenylparacresolmercaptane and their derivatives on the mastication of natural rubber. Fig. 1 shows the effect of various doses of mastication accelerators on natural rubber processing on rollers, and Fig. 2 the kinetics of mastication at 100°C. Data on the effect of temperature on the mastication on rollers are given in Fig. 3. The tested substances form the following decreasing series according to

their effectiveness on the mastication process: paratertiary butylphenolmercaptane, dimethylphenylparacresolmercaptane > zinc salts > disulfides. The greater activity of the mercaptane as compared to the zinc salts, etc., corresponds with data obtained previously by the authors in studying trichlorothiophenol, pentachlorothiophenol, orthobenzamide thiophenol and their derivatives (Ref. 1,2). It was further found that the mastication of natural rubber in the presence of paratertiary butylphenolmercaptane, dimethylphenylparacresolmercaptane, their zinc salts and disulfides is hardly effective on the tendency of the breaker mixtures to scorching, or on the vulcanization rate and physico-mechanical properties of their vulcanizates. The authors state in conclusion that for industrial application only the zinc salts of mercaptanes are of interest, since mercaptanes are toxic and easily decompose when stored, and the disulfides have a resin-like consistency. There are 3 sets of graphs, 1 table and 3 references:

S/0138/64/000/009/0025/0027

AUTHOR: Etingon, I. I.; Borodushkina, Kh. N.; Kamenskaya, S. A.; Tikhacheva, Ye. P.

TITLE: Possible use of dimethylaminomethyl phthalimide as a secondary accelerator of vulcanization

SOURCE: Kauchuk i rezina, no. 9, 1964, 25-27

TOPIC TAGS: vulcanization, accelerator, dimethylaminomethyl phthalimide, diphenylguanidine, phthalic anhydride, N-nitrosodiphenyl amine, cushion rubber, tread rubber, tire manufacture, vulcanization accelerator / Altax, Captax, Santocure

ABSTRACT: Dimethylaminomethylphthalimide (AMP, b.p. 76-77°C) was synthesized by the reaction of phthalimide with formalin and dimethylamine, after which it was combined with Captax, Altax and Santocure and tested in mixtures based on natural and butadiene-styrene rubbers. The tabulated data for unfilled mixtures of natural rubber containing AMP and Altax are compared with the data obtained for analogous mixtures with Altax and diphenylguanidine (DPG). It was found that AMP is a secondary accelerator of vulcanization of rubber mixtures, although with a lower activity than that of DPG. The necessary increase in AMP content results in a much smaller tendency to pre-vulcanization. Vulcanized rubbers containing di-

Card 1/2

ACCESSION NR: AP4045700

methylaminomethylphthalimide have characteristics (tensile strength, elongation, hardness, aging) equivalent to those of vulcanized rubbers containing diphenylguanidine except for the modulus of elasticity, which is somewhat higher. For some mixtures, AMP can completely replace diphenylguanidine and phthalic anhydride or N-nitrosodiphenyl amine. The experimental data for natural cushion rubbers (with 25 parts by weight of furnace gas black and 15 parts by wt. of channel black for 100 parts of rubber) and for tread rubbers (containing 50 parts by wt. of KhAF furnace black for 100 parts by wt. of rubber) based on butadiene-styrene with different amounts of components (Altax, Santocure and AMP) are tabulated and compared. The variation in properties depending on the amount of accelerators is discussed. "T. Gendler took part in the experimental work." Orig. art. has: 4 tables and 1 structural formula.
