TITLE: Conditions for manufacturing pressed articles from the aluminum alloy D16 (D16) having a high strength at room and elevated temperatures

SOURCE: Fridlyander, I.N., V.I. Dobatkin, and Ye.D. Zakharov, eds.
Deformiruyenyye alyuminiiyevyye splavy; sbornik stately.
Moscow, 1961, 64 - 75

TEXT: The alloy D16 has a high strength at room temperature and weakens relatively little at higher temperatures. It can, therefore, be used for articles which undergo heating during operation. It is known that the strength of pressed articles made of D16 may vary from 40 to 60 kg/mm², this variation depending on the composition, production and the heat treatment. Because D16 was found suitable for use in articles working at elevated temperatures it was necessary to establish the possible variations in strength on heating pressed articles made of this alloy. According to PCCT4784-49 (GOST-4784-49) the con-

Card 1/3

Conditions for manufacturing pressed ... S/EE9/31/000/000/000/000
D205/D303

tent of alloying elements may vary in D16 as follows: Cu - 3.8 to 4.9 %, Mg - 1.2 - 1.8 %, Mn - 0.3 - 0.9 %. The influence of changing composition was investigated by testing samples of the lower (I), average (II) and higher (III) additions of the alloying elements (I - 3.9, 1.2, 0.56; II - 4.5, 1.5, 0.57; III - 4.7, 1.8, 0.8 of Cu, Mg, Mn respectively). Three types of profiles were industrially produced from the alloys: one with walls 2 mm thick, the second with walls 15, 8 and 4.5 mm thick and the third, a large profile of 30 - 40 mm walls. They were produced by homogenizing the ingots at 490°C and deforming to the extent of 1.5 - 2 %. All profiles were tested for tensile strength at room and elevated temperatures. Conclusions: The pressed articles of D16 have a high strength at room temperature provided the non-recrystallized structure is present. This difference in the strength caused by structural differences is decreased or entirely removed by heating to temperatures above 150°C. The highest strength in the 20 - 300°C range was obtained at 4.2 - 4.9 % Cu, 1.5 - 1.9 % Mg and 0.6 - 0.9 % Mn. This increase in strength was accompanied by a decrease in the plasticity. Profiles of the A.16 TPP (D16TPP) brand are recommended for use at elevated temperatures, these profiles con-

Card 2/3

D205/D303

taining the alloying elements in the above specified limits. The mechanical properties of artificially aged articles of D16 are almost independent of the pressing condition. The microstructures of recrystallized and non-recrystallized, naturally aged, pressed profiles differ considerably in grain size. After artificial ageing the structure becomes uniform with a very fine grain. There are 5 figures, 3 tables and 2 Soviet-bloc references.

TITLE: Influence of aluminum purity on the mechanical properties
and heat-resistance of aluminum alloys

SOURCE: Fridlyander, I.N., V.I. Dobatkin, and Ye.D. Zeldurov, eds.
Deformiruyemye alumininiye splavy; sbornik statey.
Moscow, 1961, 30 - 43

TEXT: Owing to contradictory data published on the influence of Fe
and Si impurities on the properties of Al alloys it was interesting
to clarify this point. 7 aluminum alloys A16, A19, A14-1, A20,
A21, B95 and AM-6 (D16, D19, AK4-1, D20, V95, MG6) were prepared
using aluminum metal of 3 kinds: Al, ACO and AV000 (Al, ACO and
AV000), in graphite crucibles, by smelting in electrical furnaces.
The thermal regimes applied were as follows: D16, D19, homogenized at
480°C for 24 hours, quenched from 500°C and naturally aged; D20, ho-
mogenized at 520°C for 16 hours, hardened from 535°C, aged at 170°C

Card 1/2

Influence of aluminum purity on ...

S/689/61/000/CCC/005/030
D205/D303

for 10 - 16 hours; D21 and AK4-1, homogenized at 500°C for 24 hours, quenched from 525 - 535°C, aged at 180°C for 10 - 16 hours; V95 and V96, homogenized at 455°C for 24 hours quenched from 470°C, aged at 140°C for 16 hours; A 1126 homogenized at 480°C for 24 hours and annealed at 575°C for 1 hour, followed by cooling in air. The specimens prepared from the alloys were tested for tensile strength, long range strength and repeated static load. The results are tabulated, the main conclusions being summarized below. The strength of pressed rods of D16 and D19 alloys at room temperature increases slightly with increasing purity of the Al. The mechanical properties of D20 and D21 forgings were practically independent of the purity of the aluminum employed in the alloy preparation. In the AK4-1 forgings, the strength decreased with the increase of aluminum purity. The long range strength of all alloys decreased with the increase of purity. The decrease of impurities content in the V95 and V96 alloys somewhat decreased the number of cycles before breaking under repeated static loading. The results do not justify the use of very pure aluminum (AVOCO) in order to increase the heat-resistance of sheets and forgings made of aluminum alloys at the temperature of 200°C. There are 8 tables and 2 references: 1 Soviet-bloc and 1 non-Soviet-bloc.

TITLE: The effect of aluminum purity on the mechanical properties and heat-resistance of aluminum alloys

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 5, 1962, 71, abstract 51432 (V sb. "Deformiruyemyye alyumin. splavy", Moscow, Oborongiz, 1961, 30 - 43)

TEXT: The authors studied the effect of Fe and Si admixtures upon the properties of deformed Al-alloys at room and higher temperatures. For the preparation of grade 16, 19, AKЧ -1 (AKCh-1), D 20 (D20), D 21 (D21), B 95 (V95) and AMг 6 (AMg6) alloys, three Al grades were used, namely: Al A00, and AB000 (AV000); Mg- and Zn-metal, and addition-alloys Al-Cu, Al-Mn, Al-Ti, Al-Ni, Al-Fe. The strength of pressed rods made of D16 and D19 alloys increases somewhat at room temperature with a higher purity of the initial Al. The mechanical properties of forgings in short-lasting tension of D20 and D21 alloys, do practically

Card 1/2

The effect of aluminum purity on...

S/137/62/000/005/104/150
A006/A101

not depend on the initial aluminum grade. The strength of AKCh-1 alloy forgings decreases with higher Al purity. The endurance strength of semi-products of all alloys decreases with a higher purity of the initial Al. A decrease in contamination of V95 and V96 alloys reduces somewhat the number of cycles until the breakdown in repeated static-loading tests. It is not expedient to use high-purity Al (AV000) to raise the heat-resistance of sheets and forgings made of Al alloys at 200°C.

TITLE: Conditions for obtaining D 16 (D16) aluminum-alloy extruded articles offering high strength properties at room and elevated temperatures

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 5, 1962, 72, abstract 51435
(V sb. "Deformiruyemye alyumin. splavy", Oborongiz, 1961, 64 - 75)

TEXT: The authors studied extruded D16-alloy sections containing alloying elements in a low range (3.9% Cu, 1.2% Mg, 0.36% Mn), a high range (4.7% Cu, 1.8% Mg, 0.8% Mn) and a medium range (4.5% Cu, 1.5% Mg, 0.5% Mn). Under industrial conditions sections of three types were manufactured: A - a corner with a 2 mm thick shelf; B - a corner with 15.8 and 4.5 mm thick shelves, and C - a large section with 30 - 40 mm thick shelves. The following technique was used: homogenizing of ingots at 490°C for 8 hours, extrusion of ingots at 390 - 430°C; quenching of sections at 500°C; tension-straightening with 1.5 - 2% residual deformation. Tests of mechanical properties at room temperature were made after heating at 200, 250 and 300°C during 1 - 100 hours. The mechanical properties

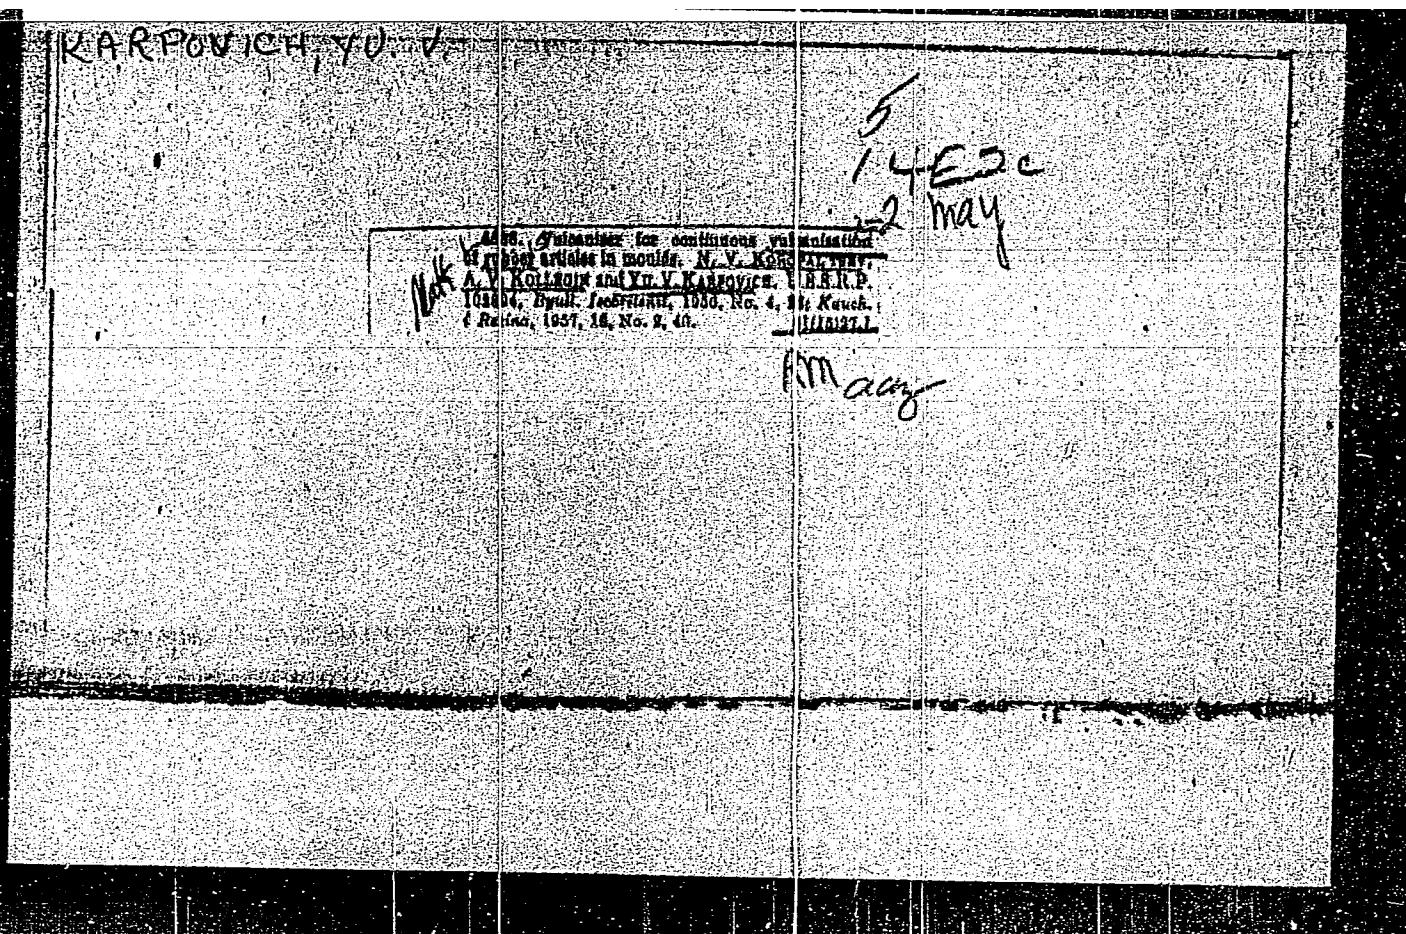

Card 1/3

S/137/62/000/005/106/150
A006/A101

Conditions for...

at high temperatures were determined after holding at the test temperature for 0.5, 20 and 100 hours. Extruded D16-alloy parts having a non-crystallized structure show high strength at room temperature. The difference in the strength of extruded articles, determined by the structure (recrystallized or non-crystallized) decreases or vanishes entirely after heating up to temperatures $> 150^{\circ}\text{C}$. Highest strength in the $20 - 300^{\circ}\text{C}$ temperature range is attained at a content in alloy D16 of 4.2 - 4.9 Cu; 1.5 - 1.9 Mg and 0.6 - 0.9% Mn. An increase in the strength is accompanied by a reduced ductility. It is recommended to extrude the articles from a non-homogenized blank at $400 - 440^{\circ}\text{C}$. The minimum properties at room temperature are: σ_b 48 kg/mm²; $\sigma_{0.2}$ 34 kg/mm²; δ 7%. The difference in the strength determined by the extrusion effect and connected with the extrusion technique, decreases sharply after artificial aging ($190^{\circ}\text{C} - 6$ hours). Repeated heat treatment (quenching and natural aging) reestablishes the difference in the strength. The mechanical properties of extruded parts in artificially aged state do almost not depend on the extrusion technique. It is assumed that one of the causes of the extrusion effect is the arising of slip obstacles along the planes, oriented along the extrusion direction; this is

Proizvodstvo rezinovykh izdeliy metodom lit'ya pod davleniem
(Manufacturing of Public Products by Compression Molding)
Leningrad, Goskhimizdat, 1959. 162 p. 3,500 copies printed.

Ed. (Title page): D. G. Traber, Candidate of Technical Sciences;
Tech. Ed.: Ye. Ya. Erlikh.

PURPOSE: This book is intended for workers of the rubber industry using rubberized metal parts. It may also be useful for students of schools of higher technical education studying the manufacture of rubber products.

COVERAGE: The authors review methods of compression molding of uncured compounded rubber and describe various machines and equipment used in this process. Principles and flow schemes of compression molding of uncured compounded rubber are explained, and various rubber molding presses illustrated. The flow of

Card 1/4

Manufacturing (Cont.)

SOV/3215

compounded rubber is analyzed by graphs and equations. Examples of computing the compounded rubber flow are given along with designs of different types of molding presses, their various parts and fittings. Equipment used for vulcanizing rubber, such as autoclaves, boilers and apparatus of continuous vulcanization are described and illustrated as well as machines employed for extruding rubber parts and cores from molds. Devices used for controlling the molding and vulcanizing processes are reviewed and the setup of a rubber manufacturing plant is outlined. The authors emphasize numerous advantages of the compression molding method. The appendix contains regulations and instructions as to how molding presses and equipment should be operated and handled with observation of safety precautions. There are 22 references: 14 Soviet and 8 English.

TITLE: Cryoscopic method for determining the purity of individual compounds

CITED SOURCE: Sb. Metody* issled. produktov neftepererabotki i neftekhim. sinteza. L., Gostoptekhizdat, 1962, 81-95

TOPIC TAGS: purity determination, analysis, cryoscopic analysis, organic analysis, cryoscopic constant, benzene, benzene purity determination

TRANSLATION: A method is described for the cryoscopic determination of small concentrations (0.001-1.0 mol.%) of impurities in organic compounds, and formulas are presented which can be used for calculating the content of impurities from the results of the measurements. The apparatus used for the purity determinations consists of a vessel with double walls, between which there is a vacuum (residual pressure of 10 mm. Hg), a testtube containing the material to be analyzed, a stirrer which moves up and down, and an MK-54 thermistor with a temperature coefficient of 40-50 ohms/degree. The resistances of the thermistor are measured by an MOD-54 bridge. After washing and drying the testtube, it is filled with the

Card 1/3

ACCESSION NR: AR4015637

material to be analyzed and placed into the double-walled vessel, in which a vacuum is then created (residual pressure of 2-10 mm Hg). The vessel is then placed in a Dewar flask containing a cooling fluid, along with the stirrer and a timer. The resistance of the thermistor is then measured, initially every minute and then, after the onset of crystallization, every 30 seconds until stirring stops. A cooling curve is plotted in R, z coordinates from the data obtained, where R is the resistance of the thermistor and z is time. On the cooling curve, three points are selected: G(R_g, z_g), H(R_H, z_H) and I(R_i, z_i) at which $z_H - z_g = z_i - z_H$. By extrapolating the equilibrium part of the curve until it intersects the vertical axis, one obtains z_0 (the time of onset of crystallization). From the formulas $X_0 = 1/(lgR_0 + lgK)$ and $X_f = 1/(lgR_g - lgK)$, where K is the thermistor constant, the values of X_0 , X_f and $\Delta X_0 = X_0 - X_f$ can then be found. The experiment is then repeated with a known amount of impurity and new values for $\Delta X_{f1} = X_0 - X_{f1}$ are obtained in the same way. The value of a (the amount of impurity weighed out in grams) can then be determined from the formula $a^2 [(1-D)(1-k)] + a [(1-k)(Db+x) + kDx] - kxD_b = 0$ where b is the weight of the compound being analyzed in grams, $D = M/M_0$, M is the molecular weight of the impurity and M_0 is the molecular weight of the pure substance, and the amount of original impurity can be determined from the formula $m_1 = a/(a+bM/M_0)$. The constant A' for the compound for the given thermistor can be determined from the equation $m_2 = A'(X_0 - X_f)$ where m_2 is

Title : The Internal Infection of Tomato with Bacterial Canker
as a Communicatory Factor.

Orig Pub : Dokl. VASKhNIL, 1957, No 6, 22-26

Abstract : In order to investigate the role of the internal infection of seeds in the spread of tomato bacterial canker, a study was made with seeds collected from fruits 1) having internal infections, 2) having infected fruit stems, 3) from heavily attacked plants, and 4) from plants having moderately damaged stalks. To detect Corynebacterium michiganense (E. Smith) the seed surfaces were disinfected with mercuric chloride (1: 1000 and 1: 3000), the residual bactericide was removed by soaking in sterilized water for 3½ to 4 hours (H_2SO_4 depressed seed germination,

Card 1/3

and Zbarskiy bactericide was not removable by soaking away the left-over bactericidal properties). After disinfection the seeds were gone over by microscope for bacteria and planted on MPA, MPB and bean agar. 6300 seeds were analyzed and 450 planted. Two bacterial cultures were divided, according to the external appearance and the biochemical properties conformable to C. michiganense, which proved however to be incapable of infecting potted tomatoes upon inoculation. A part of the seeds were used in field tests where the cultivations preceding the tomatoes were flowering crops, thus excluding the transmission of the disease through the soil. In three years of field tests the bacterial canker appeared in a total of 0.26-0.73% of the plants as a result of the internal infection of the seeds. Such a low percentage of infection arising when disinfected seeds from obviously sick plants were sown indicates that the surprising outbreaks of tomato

bacterial canker may be only partially attributed to the internal contamination of the seeds. -- V.V. Abramovich.

"vacuum-Tube Oscillator for Technological Purposes,"
M. I. Karpovskiy, 8 pp

"Radiotekhnika" No 6

Examines certain vacuum-tube oscillator circuits
which do not require rectified plate supply but still
attain high efficiency. Takes up theoretical as-
pects, followed by experimental results. Test oscil-
lator delivered 1,300 watts output with 2,730 watts
input, plate efficiency 75%. Submitted 12 Aug 49.

AUTHOR: Karpowicz, M.TITLE: The field of velocities of centroids of B-class stars in the Local system

PERIODICAL: Referativnyy zhurnal, Astronomiya i Geodeziya, no. 9, 1962, 36, abstract 9A284 ("Postępy astron.", 1961, v. 9, no. 4, 217 - 223, Polish)

TEXT: The article contains a list of some publications dealing with the study of the Local system. Tables of galactic longitudes are presented for rotational centers of various spatial groups of spectral binaries and single stars of spectral classes B0-B9, which confirm the existence of the Local system. The results of determining the position of the Gould belt are presented (inclinations and longitudes of the node):

Stars	B0-B9	B2-B5
i	$14^{\circ}, 8 \pm 4^{\circ}, 6$	$8^{\circ}, \pm 2^{\circ}, 1$
II	$270^{\circ}, 3 \pm 25^{\circ}, 1$	$276^{\circ}, \pm 17^{\circ}, 8$

The field of velocities of centroids of...

The parameters of the Local system rotation are investigated by means of Botlinger-Pilowski formulae using the B-stars with the known radial velocities (Wilson's catalogue) and proper motions (Boss's catalogue). The galactic longitude of the center of the Local system was adopted to be 240° . The values of Kamm's function are calculated and presented. The distance to the center of the Local system is 90 ± 27 pc, and the period of one revolution is 4.5×10^8 years (B2-B5 stars). A conclusion has been drawn that stars of class B do not constitute a homogeneous subsystem, but composed of several subsystems different in kinematic respect. There are 14 references.

statystycznych - Karpowicz R., Klin. Psychiat. A. M., Łódź - NEUROL.
NEUROCHIR. PSYCHIAT. POL. 1957, 7/3 (389-393) Tables 6

The effectiveness of the treatment of schizophrenia was determined by the method of Wilezkowski. The statistics comprise 295 schizophrenic patients, admitted during the period from January 1st 1954 till December 31st 1954 and observed from January 1st 1954 to June 30th 1955 in the hospital. The calculation results were represented in 6 tables. In the general material, remissions were found in 12.9% of the cases, remissions and improvements together in 63.5%. Moreover, the obtained results prove that treatment used should begin in the earliest possible period of schizophrenia and the prognosis is better the younger the patient is.

TITLE: Electronic device for automatic exposure determination for printing aerial
photographs?

SOURCE: Geodeziya i kartografiya, no. 10, 1964.

TOPIC TAGS: aerial photograph, exposure meter, photographic process, photographic printing, photographic material

ABSTRACT: An electronic device for automatic exposure regulation for developing black and white aerial photographs has been developed at the Aerofotograficheskaya laboratoriya TsNIIGAiK (Aerophotographical Laboratory TsNIIGAiK), described by A. N. Uspenskiy (Kopirovalnyye pribory* s avtomaticheskoy intenzivnostyu pri pechati aerosnimkov. Sbornik trudov TsNIIGAiK, 1964, No. 149). This system consisting of a laboratory electromotor. At the input of an alternating current amplifier controlling a reversing electromotor are set measuring

37-42

intensity varying with the density in the lamp potential. This

and compensating selenium photoelements linked through a differential scheme. The compensation photoelement is illuminated by a standard lamp independently of network potential variations; the measuring photoelement is illuminated by a light from the duplicator lamp passing through the negative and photopaper. Exposure is determined and a signal is input to the electronic amplifier. The polarity of this signal sets the speed of electromotive rotation which, in turn, fixes the potential of the duplicator lamp. Also described is a device for determining exposure through the use of photoresistors. The network causes increases in the light stream with darker photoresistance, and vice versa. Wiring and element diagrams of both networks are shown, along with photographs of the devices. Orig. art. has: 6 figures.

TOPIC TAGS: combustion, solid propellant combustion, solid propellant, combustion instability, deflagration to detonation transition, DEFLAGRATION, DETONATION, EXPLOSIVE CHARGE

ABSTRACT: The development of combustion instability and the deflagration-to-detonation transition was studied in a constant volume bomb by pressure recording and high speed photography. The hexogen samples were compacted into plexiglass cases and ignited by an electric wire or a powder charge. The results showed that the deflagration-to-detonation transition under increasing pressure takes place according to the following order: normal combustion; perturbed combustion; ejection of particles into the flame zone, which is accompanied by interruption of luminosity; accelerated combustion of the ejected particles, which generates a pressure increase above the burning surface; and gas penetration into the pores, which leads, in case of a pure explosive, to a detonation and, in case of an explosive phlegmatized with

AUTHOR: Bobolev, V. K.; Karpukhin, I. A.

TITLE: Physicomathematical properties of eutectic mixtures of explosives

SOURCE: AN SSSR, Doklady, v. 151, no. 1, 1963, 155-157

TOPIC TAGS: explosives, TNT, tetryl, PETN, eutectic mixtures, impact strength, impact sensitivity, explosion temperature, melting point

ABSTRACT: The use of eutectic mixtures of explosives to lower the sensitivity of the components to mechanical action has been investigated. On the basis of theoretical computations and the results of previous studies, it was postulated that widening the interval between the explosion temperature and melting point of an explosive by formation of a eutectic mixture would lower sensitivity to mechanical action. This postulate was tested experimentally by determining the impact strength and impact sensitivity of TNT-tetryl and PETN-tetryl mixtures for the entire range of compositions. It was found that, as in the case

Card 1/3

L 10776-63

ACCESSION NR: AP3003522

of individual explosives, the dependence of impact strength on melting point is described by the equation, $\sigma = kT_m$, where $k = 5.3 \text{ kg/cm}^2\text{C}$, σ is the impact strength, and T_m is the melting point. To determine the relationship between physicomechanical properties and impact sensitivity, explosion-frequency tests were conducted. A 66/34 TNT-tetryl eutectic mixture melting at 68.8C exploded in 8% of the cases; a 67.5/32.5 PETN-tetryl mixture melting at 104C, in 24%. In contrast, a PETN-tetryl mechanical mixture in the same ratio as the eutectic exploded in 60% of the cases. It was concluded that the sensitivity of explosives to mechanical action can be lowered by preparing eutectic mixtures. It is also suggested that the development of multicomponent eutectic systems will lower this sensitivity still further by sharply changing the physicomechanical properties. Orig. art. has: 2 figures, 3 formulas, and 1 table.

TITLE: Combustion of porous explosive charges

SOURCE: Nauchno-tehnicheskiye problemy goreniya i vzryva, no. 1, 1965, 44-51

TOPIC TAGS: detonation deflagration transition, solid propellant explosion, combustion, combustion instability

ABSTRACT: Previous experiments have shown that the transition from deflagration to detonation in porous propellants is connected with an unbalanced formation and removal of gas from the pores. The transition from deflagration to detonation in hexogen charges of 50—360 μ particle size, with and without the addition of paraffin wax, has been studied by pressure recordings and high-speed photography. Normal combustion took place under constant pressure for about 3 sec, then the burning velocity increased, and gradual transition to a perturbed combustion regime occurred, characterized by luminosity pulsations. The lengths of the periods of low luminosity increased with increasing particle size. The following mechanism is proposed. Normal combustion takes place only when the hot gases penetrating into the pores do not heat the grain to the gasification temperature to a depth exceeding that of the thermal layer. If this depth is exceeded, transition takes place. Paraffin wax acts as a

thermal barrier in the penetration of combustion products into the pores, and thus
retards the transition from deflagration to detonation. Orig. art. has: 6 figures.
