

AUTHOR: Kvinikhidze, G. S. SOV/20-122-2-39/42

TITLE: Development of the Epithelium Lining of the Oesophagus in Domestic Fowl (Razvitiye epitelial'noy vystilki pishchevoda domashnikh kur)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol 122, Nr 2, pp 304-307 (USSR)

ABSTRACT: The formation and the development of several organs in the embryogenesis is characterized by a sequence of the histological structures which is governed by definite rules (Ref 2). This was also reported for the human oesophagus (Refs 7, 8). The author investigated hen embryos (eggs which were incubated for 3, 4, 5, 7, 9, 10, 11, 12, 14, 15, 16, 17 and 19 days) and chicken at the age of 1 day and of 1 month in order to find out whether a sequence of structures occurs in the covering epithelium in the hen oesophagus. The oesophagus mucosa of embryos 3, 4, and 5 days old is free from folds. The oesophagus is lined with an epithelium which consists of oblong prismatic, 1 - 2 rows of cells. Mitoses only occur at the surface (Fig 1). Sometimes the epithelium fills the lumen of the oesophagus because of its rapid growth.

Card 1/4

SOV/20-122-2-39/42

· Development of the Epithelium Lining of the Oesophagus in Domestic Fowl

From the 9th to the 10th day of incubation from 4 to 5 longitudinal folds appear in the mucosa. In embryos 11 - 12 days old the epithelium starts to rearrange, forming several (2 - 4) layers. Now mitoses are not found on the surface. In embryos 13 - 16 days old ciliated and mucous cells appear at the surface of the multi-layered epithelium which exhibits an unequal thickness. These cells form an almost uninterrupted layer. The number of mucous cells increases towards the stomach (Fig 2). The oesophagus of an embryo which is 15 days old is filled with swallowed albumen. Epithelial gemmules originate from the basal surface of the mucous epithel and penetrate into the underlying connective tissue. These gemmules consist of firm cells forming the rudiment of tube-like mucous glands (Fig 2). Embryos at an age of 17 - 19 days already show a mucosa with 8 - 10 cell layers, which shows well developed folds. The ciliated cells are placed as individual islands at the surface of the epithelium (Fig 3). They gradually flatten out, disintegrate and are peeled off. Mitoses are exclusively found at the basis of the layer. Now the tubular mucous glands are developing from the mentioned gemmules. They are lined with a prismatic epithelium and be-

Card 2/4

SOV/2c-122-2-33/42

Development of the Epithelium Lining of the Oesophagus in Domestic Fowl

gin to exsecrate mucus. The epithelial lining of a chicken at the age of 1 day is multi-layered and plane. Disintegrating ciliated cells, are found only very rarely. The tubular mucous glands are well developed and are lined with one-layered epithel consisting of oblong prismatic cells (Fig 4). The walls of some mucous glands begin to form folds, with the underlying connective tissue taking part in this process. In chicken at the age of 1 month the lining epithel is in the process of cornification. Large epithelial ramparts appear, which are covered by many small epithelium projections. Uvula from connective tissue are interposed in between, exhibiting well developed collagenous fibers. This is the complicated transformation process of the cover epithelium. Hitherto ciliated epithelium was reported only in the human oesophagus (Refs 1, 7 - 9). The ciliated cells are by some authors considered to be a recapitulation phenomenon (Refs 4, 7, 8), by others it is considered to be exclusively an embryonal adaption (Ref 1). The author follows the first assumption. There are 4 figures and 9 references, 8 of which are Soviet.

TITLE: Scattering of slow neutrons in antiferromagnets with weak ferromagnetism

SOURCE: Fizika tverdogo tela, v. 7, no. 4, 1965, 1110-1113

TOPIC TAGS: neutron scattering, slow neutron, spin spin scattering, spin phonon scattering, inelastic scattering

ABSTRACT: The authors analyze the line broadening of inelastic scattering of neutrons in antiferromagnets with weak interaction, brought about by mutual scattering of spin waves and the scattering of spin waves with absorption or emission of phonons. Since the average lifetime of the spin wave with activation energy is exponentially small at sufficiently low temperatures, the analysis is limited only to the line broadening of inelastic scattering of neutrons with absorption or emission of non-activation spin waves. Both the broadening due to the spin-spin interaction and the broadening due to the spin-phonon interaction are found to be proportional to the square of the spin wave energy. The ratio of these broadenings is much

The biochemical picture as an indicator of the state of oxidation-reduction processes in hypertensive disease. N. K. Kvirkadze and A. A. Darblishvili. *Trudy Inst. Klin. i Zazpi. Kardiol., Akad. Nauk Gruzii, S.S.R.* 2, 413-24 (1953); *Referat. Zhur., Biol.* 1955, No. 1779.—Dogs received intravenous injections of norepinephrine, and their sciatic nerve was stimulated. As the blood pressure rose to the max., the blood content of lactic (I) and pyruvic (II) acids rose, as did that of oxidized glutathione; O₂ depletion increased. In the early stages of hypertension (III) the content of glutathione was lowered. It again rose during stages 2 and 3 of the disease. The content of I varied and reached its max. in patients with stable blood pressure in the reversible form of III and was again lowered in stage 3, coincident with the loss of autoregulatory processes of the organism. During the functional stage of III the content of II also varied widely, but it ultimately reached a high level. This high concn. of II indicated that its normal course of metabolism had been disturbed due to a condition of neurodystonia and damaged internal organs. As III progresses the amino acids are increased due to the breakdown of tissue deamination processes, and the catalytic index remains at or below the lower limit of the normal range, probably due to an increased tonus of the sympathetic nervous system. In 78% of the patients the O₂ depletion of the blood serum exceeds that of the normal in the pre-hypertonic stage when no other symptoms of deviation are discernible. The accumulation of products of incomplete oxidation disturbs the normal course of the body economy, which may affect (via the interoceptive channels) the central nervous system, which in turn may aggravate the disease.

Abstract : In rabbits with reflexogenic, adrenal and renal hypertension, the consumption of O₂ by brain tissue was reduced, while that of liver tissue remained unchanged. Renal tissue respiration decreased in reflexogenic and adrenal hypertension and increased in renal hypertension. The latter phenomenon the author associates with the accumulation in the ischemic kidneys of the animals of incompletely oxidized products,

myocardium of killed rabbits. After the extract was incubated in a O₂ atmosphere with a nutritive mixture containing anorganic P, the loss of P in the mixture was determined with the method of Fiske and Subbarow. If the extract was prepared from the heart of a healthy rabbit, the amount of mineral P in the mixture decreased on the average by 72.23 percent, and by 94.64 percent after 30 minutes. In extracts prepared from the myocardium of rabbits suffering from hypertension, the P content decreased by 46.13 percent after 15 minutes. The loss of P almost ceased entirely during the next 15 minutes. The delay of aerobic phosphorylation processes is related to changes of the physico-chemical protein structure in tired cardiac muscle, as a result of which the active non-soluble ATP-ase enters the extract, thus causing a regeneration of anorganic P. On the other hand, the activity of ferment

The advantages of the preparation of clay dispersions according to the method of A. I. Tsvirko and V. I. Kuznetsov, N. I. Shatov, *Neftegaz. Akts.* 1939, No. 8, 27-30; Akim. Refract. Chur. 1939, No. 12, 83. The use of clay dispersions of the Moscow Petroleum Inst. investigated the new method for the prepn. of clay dispersions consisting of a preliminary kneading of the clay dough with 41-7% of water. The Buguruslan, Zykha and Pirsagan clays as well as the sea (Caspian) and river (Buguruslan) waters were investigated. Pre-

liminary chem. analyses showed that the variations of the contents of SiO_2 are from 81.40 to 83.01% and of those of Fe_2O_3 are from 5.08 to 6.13%. The contents of Na_2O and K_2O were 4.88% in the Pirnagat clay and 2.63% in the Bugaruslan clay. The contents of compds. were 6.00% in the Bugaruslan clay, 4.01% in the Zykha clay and 5.03% in the Pirnagat clay. The degree of dispersion of the particles in the clay and in the aqueous clay dispersions remained nearly const. The optimum amt. of water to be added to clay for obtaining clay dough which produces optimum clay dispersions is 47% for the Zykha and Bugaruslas clays and 42% for the Pirnagat clay. A 100% addn. of water produces poorer dispersions. A preliminary swelling does not improve the quality of the dispersions, but accelerates the process of preparation. The quality of dispersions prep.

from river water followed by an addn. of sea water did not differ from those prep'd. with sea water alone.

Geology

New method for the investigation of clays and the preparation of clay solutions. V. L. Kvirkashvili AND A. I. Tsaturyan. Rabochii Rezh. 1960, No. 7, pp. 5-6; Khim. Referat. Zhur., 4 (1) 101 (1961).—Thixotropy is an important property of clay suspensions. Because of it, the clay retains the drilled rock in a suspended state. A new method for the preparation of clay suspensions consists in mixing the clay with 20 to 30% of its weight of water and blending it until it forms a thick paste. The amount of water depends on the colloidality of the clay. The clay paste is further mixed for 10 to 15 min., and water is then added to establish the right viscosity. M.Ho.

Use of Aktangel-beatoensis clay as coagulant for water clarification and an antiseptic. V. L. Kvirikashvili
Bull. Acad. Sci. Georgian S.S.R.S.R. 4, 777-80 (1943) (in Georgian and Russian).—The fine-disperse, high-swelling, trioxotrichite clay of the compn. SiO_2 01.27, Al_2O_3 17.58, Fe_2O_3 0.28, CaO 1.24, MgO 3.04, Na_2O 1.20, NaClO 0.81, K_2O 1.04, moisture 13.04, loss on calcination 0.21%, particle sizes of 0-1.12, 1.12-2.2, 2.2-3.9, 3.9-17.4, 17.4-300 μ (including sand), with stabilizer were 77.0, 2.8, 2.2, 1.2, 10.8% resp., without stabilizer 60.0, 3.5, 10.9, 5.2, 19.9% resp. Added in amnts. of 20 mg. per l. it clarifies water by coagulation, particularly in mixt. with lime, as effectively as $\text{Al}_2(\text{SO}_4)_3$; moreover, it lowers the permanent hardness. The action consists in ion exchange against the Na and K ions of the clay. Coagulation was most successful with a hydrate alkalinity of 0.84-1.40° (German grades), carbonate alkalinity 1.12-1.40°. Anticorrosion action is due to removal of Mg salts into the ppt.; this effect is brought about by very small amts. of the clay, 20-180 g. per ton of water; 50 g./ton is recommended as a basis. The action depends entirely on the high dispersity of the clay; coarse fractions are ineffective.

Action of sodium carbonate and sodium pyrophosphate on clay suspensions. V. I. Kvirikashvili (P. G. Melikishvili). Inst. Chem., Acad. Sci. Georgian S.S.R., Tiflis. *Kolloid-Zhur.* 16, 421-4 (1954).—The static and the dynamic yield stresses θ of a bentonite clay (I) and a nonbentonite clay (II) were raised by addn. of Na_2CO_3 (0.02-0.5%) to their suspensions in H_2O . However, the rate B of moisture loss was raised by Na_2CO_3 for I and lowered for II, which shows that Na_2CO_3 coagulated I and dispersed II. $\text{Na}_4\text{P}_2\text{O}_7$ lowered both B and θ of II, i.e. stabilized it. Also in *Colloid J. (U.S.S.R.)* 16, 421-4 (1954) (Engl. translation).

Abstract : difference $O_{st} - O_d$, where O_d and O_{st} are the structure strengths immediately after stirring and after a prolonged staying. The structures of I, formed by particle linkage with their ribs and ends, are thixotropic, which is revealed in a high $O_{st} - O_d$, O_d being little. The II particles, linking with their planes, produce little-thixotropic structures with a higher O_d . An addition of saponin increases the hixotropy of II and decreases that of I. An introduction of soda, which acts hydrating on II and dehydrating on I, increases O_d and O_{st} in both cases.

TITLE: Contact catalytic transformation of cyclohexane and methylcyclohexane in the presence of a natural glauconitic catalyst

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 16, 1962, 385, abstract 16L17 (Soobshch. AN GruzSSR, v. 27, no. 6, 1961, 671-678)

TEXT: An investigation was carried out on the catalytic properties of natural glauconitic sand (without acid activation) during transformation of cyclohexane (I) and methylcyclohexane (II) at 570-540°C and at atmospheric pressure. The main trend of the reaction is to dehydrogenate I and II to C₆H₆ and C₆H₅CH₃; To an insignificant extent the CH₃ group splits off forming C₆H₆. There is no isomerization of I or II with contraction of the cycle, no hydrogenation with formation of n-hexane or n-heptane, and no formation of higher homologues C₆H₆. TITLE: The electrical activity of the hippocampus in ontogenesis

SOURCE: AN GruzSSR. Institut fiziologii. Trudy, v. 14, 1965. Sovremennyye problemy deyatel'nosti i stroyeniya tsentral'noy nervnoy sistemy (Present problems of the activity and structure of the central nervous system), 107-120

TOPIC TAGS: hippocampus, CNS ontogenesis, hippocampus's electrical activity, hippocampus development, ontogenesis

ABSTRACT: Postnatal development of electrical activity in the hippocampus was studied in newborn rabbits. Three stages were distinguished. During Stage 1 (until 6 to 7 days after birth) the spontaneous electrical activity of the hippocampus is not differentiated from that of the neocortex: low voltage slow waves predominate in both. Direct stimulation of the hippocampus evokes potentials not only on the stimulated side, but in the opposite half of the hippocampus and in the neocortex (especially the visual cortex) as well. Surface negativity of the evoked potential lasts approx. 100 msec. Remoter evoked potentials are preceded by a small positive potential. Rhythmic stimulus sharply diminishes, then suppresses the negative waves. During Stage 1 convulsive discharges in the hippocampus are not seen. During Stage 2

Card 1/2

L 22214-66

ACC NR: AT5024230

(6-7 to 17-20 days after birth), the amplitude of the basic rhythm of spontaneous hippocampal activity increases and "spindle"-type periodic fast waves appear. Rhythmic stimulation during Stage 2 causes progressive augmentation of the evoked potentials (tetanic potentiation). These potentiated responses easily pass over into convulsive discharges. During stage 2, generalized cortical potentials can still be evoked by hippocampal stimulation. During Stage 3, both the spontaneous activity of the hippocampus and the potentials evoked by hippocampal stimulation are similar to those seen in adult rabbits. Hippocampal stimulation no longer evokes generalized responses in the neocortex; such evoked potentials occur in the visual cortex only. The development of hippocampal electrical activity parallels the morphological development of the neural elements of the hippocampus.
