"Surgical Remarks on Acute Hemorrhage from Gastroduodenal Ulcer."

Prague, Casopis Lekaru Ceskych, Vol 105, No 27-28, 4 Jul 66, pp 750 - 752

Abstract /Authors' English summary modified/: Diagnosis of acute gastroduodenal ulcer bleeding and diagnostic problems of esophageal varix bleeding are discussed. Acute bleeding during corticosteroid treatment and the difficulty of diagnosis of this bleeding are discussed. Hemorrhagic gastritis, like acute ulcers with profuse bleeding, usually results in an operation without a preliminary diagnosis of the actual condition of the patient. X-ray examination during bleeding is beneficial to the patient. 1 Table, no references. (Manuscript received Oct 65).

LANZER N.P.

✓ Corrosive destruction of welded joints in stainless steels of the type 18-8 in the line of  
Metavar and N. A. Lancer / J. O. Patten's  
Welding Lab. - A. V. S. N. A. Lancer  
The knife-line corrosion of welded stainless  
steel to the alloy of composition Ti or Nb + 10%  
as a result of heating the base metal above 1000 °F  
and the sub-  
sequent semi-carbides of Cr at the grain boundaries.  
To prevent knife-line corrosion it is recommended: (a) to  
increase the content of Ti or Nb + 10% in the base metal  
according to equation  $Ti \geq (C - 0.02)$ , where Ti and C  
are given in percentage by weight; (b) to subject welded  
joints to a stabilizing thermal treatment.

LANGER, N.A.

Method of Evaluating the General Corrosion Stability of  
Stainless Steel Welded Joints in Boiling Nitric Acid.

Makarov and N. A. Langer. (Zavodskaya Literatura, 1955, 21, (5), 941-943) (in Russian). Electrolytic etching in a 10% oxalic acid solution has been used to reveal the microstructure of stainless steel and stainless steel welded joints. For the former 12 V is applied for 5 min., the corresponding figures for joints being 6 V and 0.5 min. Details are given of the cell used. Microstructural results for various steels boiled for 200 h in 65% nitric acid and in electrolytically etched specimens with previous heating to 600°C in some cases are presented. Comparison of the photomicrographs with corrosion test results indicate that the electrolytic etching technique can give a preliminary evaluation of corrosion stability in boiling nitric acid. - S.X.

Title : Method of Fast Analysis of Fluxes of AN-348-A Type.

Orig Pub: Avtomat. svarka, 1956, No. 5, 80 - 83.

Abstract: A fast (2 to 3 hours) method of determination of main components of fluxes (Si, Ca, F, Mn, Fe, Al and S) without their preliminary separation was developed. For the determination of silica, 1 g of the flux is fused with 10 g of water free NaKCO<sub>3</sub> in a Pt crucible, dissolved in HCl (1 : 1), and heated to 80°; 10 ml of 1%-ual gelatin solution is added, stirred 5 min. and heated 10 min.

Card 1/4

USSR/ Analytical Chemistry. Analysis of Inorganic  
Substances.

G-2

Abs Jour: Referat. Zhur.-Khimiya, No. 8, 1957, 27228.

The precipitate is filtered off, washed 3 to 4 times with hydrochloric acid (1 : 1) and 2 to 3 times with water, roasted at 1000 to 1100° and weighed in the form of  $\text{SiO}_2$ . The accuracy is 2%. The determination of Ca in presence of  $\text{Mn}^{2+}$  and  $\text{Fe}^{3+}$  is carried out by precipitation with an excess of oxalic acid; the oxalate is titrated with permanganate (accuracy 2 to 3%). For the determination of F, 2 ml of 0.3%-ual solution of alizarin red is added and the mixture is titrated until the color changes from yellow to red. The determination of Mn is carried out by diluting 25 ml of the filtrate with 300 to 400 ml of water, adding suspended ZnO to the boiling solution, and titrating the hot solution with permanganate. For

the determination of sesquioxides, 5 g of  $\text{NH}_4\text{Cl}$  and an excessive amount of ammonia (determined with methyl red) are added to 50 ml of the filtrate, the mixture is boiled 3 min., the precipitate is filtered off, dissolved in HCl (1 : 1), and precipitated again, the precipitate is washed with water and calcined at 1000 to 1100°. Fe is determined permanganometrically, and Al is determined by the difference. For the determination of P, the sesquioxides are precipitated with ammonia, filtered off and dissolved in  $\text{HNO}_3$ . P is transferred into a phosphomolybdic complex, which is reduced with Sn dichloride and determined colorimetrically. The determination of sulfide sulphur is carried out by distilling  $\text{H}_2\text{S}$  off (treat-

TITLE: A new type of corrosion of acid resistant austenitic steel and of weld joints. (Novyy vid korrozii kislotostoykoy austenitnoy stali i svarynykh shvov). (Transcrystalline corrosion of chromium-nickel-molybdenum-copper steel X23H23M3D3, caused by compression deformations). (Transkristallitnaya korroziya khromonikele-molibdeno-medistoy st. Kh23N23M3D3, vyzvannaya deformatsiyey szhatiya).

PERIODICAL: Fizika Metallov i Metallovedeniye, 1957, Vol.5, No.1, pp. 184-186 (USSR)

ABSTRACT: Stainless and acid resistant chromium-nickel austenitic steels which do not contain titanium or niobium or tantalum suffer intercrystallite corrosion as a result of separation along the boundaries of an excess phase which is rich in chromium and results in an impoverishment in chromium of the peripheral zones. In certain aggressive media containing ions of chlorine and other haloids, austenitic steels may be affected by stress corrosion (Refs.3 to 6); under the effect of the tensile stresses and the aggressive media transcrystallite cracking of the steel may occur. In some cases trans-

Card 1/4

126-1-36/40

A new type of corrosion of acid resistant austenitic steel and of weld joints.

crystallite fracture is combined with intercrystallite fracture. The causes of this type of corrosion have not been sufficiently studied. However, it can be considered an established fact that the presence of tensile stresses in the volume of the metal is a necessary condition of transcrystallite corrosion if the metal is in an aggressive medium. No transcrystallite corrosion has been observed in presence of compression stresses. The chromium-nickel steel mentioned in the title, which is also designated by ЭИ-533 is intended for manufacturing equipment in the sulphuric acid industry. It has a high chemical stability in sulphuric acid of various concentrations of up to 75 to 80% and has a fully satisfactory stability against inter-crystallite corrosion in standard tests. Such steel also has no tendency to transcrystallite corrosion under stress. In investigating the weldability of ЭИ-533 steel the authors of this paper detected a new type of corrosion disruption of the basic metal and of the welded seam, namely, transcrystallite corrosion in

Card 2/4

A new type of corrosion of acid resistant austenitic steel and of weld joints.

sulphuric acid (boiling for 100 hours in acid of 35, 50 and 75% concentration) caused by compression deformations. Comparative corrosion tests were made on specimens of 20 x 70 mm and a width of 3.8 mm of a steel with the following chemical composition: 0.06% C, 0.8% Si, 0.33% Mn, 22.25% Cr, 23.38% Ni, 2.85% Cu, 2.80% Mo, 0.010% S and 0.01% P. A part of the specimens were tested in the as delivered state, i.e. after hot rolling and hardening to obtain austenite; the other part of the specimens were compressed by surface work hardening by means of a pneumatic chisel with a blunted end. The results are entered in a table, p.185. It was found that compression deformation causes transcrystallite corrosion and also intensifies corrosion generally. Since in making welded structures of austenitic steels it is not possible to avoid compression deformations and the resulting tendency to develop transcrystallite corrosion, the authors recommend, as a radical means of eliminating the influence of work hardening, the following heat treatment: hardening by heating for

Card 3/4

A new type of corrosion of acid resistant austenitic steel and of  
weld joints. 126-1-36/40

one hour at 1100°C followed by quenching in water or  
heating at 800°C for two hours followed by cooling  
in air. The latter form of heat treatment is  
preferable since it can be effected more easily under  
shop conditions.

TITLE: A Study of Non-Metallic Inclusions in Seams Welded Under Flux (Issledovaniye nemetallicheskikh v klyucheniya v shvakh vypolnennykh pod flyusom)

PERIODICAL: Avtomaticheskaya Svarka, 1958, Nr 4, pp 10-23 (USSR)

ABSTRACT: A brief review of different opinions on the subject is given [Ref. 1-12] to demonstrate that the influence of flux on non-metallic inclusions has been barely investigated, although the flux composition considerably affects the structure of weld metal and its mechanical properties. The experiment described in the article was carried out with the use of fluxes "AN-5", "AN-348-A", "AN-20", "AN-30" and an experimental low-silicon manganese flux, and standard electrode wire of grades "Sv-08", "Sv-08G", and "Sv-10GS". The compositions of the fluxes, wire, and the obtained weld metal are given (Tables 1-5). It was concluded that the content of non-metallic inclusions in weld metal, and the

Card 1/2

125-58-4-2/15

A Study of Non-Metallic Inclusions in Seams Welded Under Flux

general oxygen content therein, increase with increasing  $\text{SiO}_2$  content in the flux. The composition of non-metallic inclusions is determined by the flux composition and is comparatively little - affected by the composition of the electrode wire. Non-metallic inclusions originate mainly from the flux and change their composition within the weld puddle. In the conditions of intensive mixing of metal and slag in the puddle, the intensiveness of the extraction of non-metallic inclusions apparently depends less on the difference between the density of the inclusions and the metal than on the inter-phase tension on the border between them. The flux composition seems to affect the initial weld-metal structure by affecting the composition and the thickness of intercrystalline layers, and not by affecting the distribution of the non-metallic inclusions.

PERIODICAL: Avtomaticheskaya svarka, 1958, Nr 3, pp 33-41 (USSR)

ABSTRACT: Both Soviet and foreign scientists, such as G.V. Akimov, B.M. Parkin, V.N. Noyev, N.D. Sobolev and L.A. Glikman, have been concerned with the problem of cracks in boilers for some time. The Electric Welding Institute imeni Paton carried out corrosion tests of electric-slag and multilayer welded "22K"-steel specimens, put into a solution of nitrate salts (45% Ca (NO<sub>3</sub>)<sub>2</sub> and 35% NH<sub>4</sub>NO<sub>3</sub> plus water), which was recommended by Zemon and had been successfully used by S.G. Vedenkin. The authors come to the conclusion that electric-slag welded joints have a higher resistance to caustic brittleness than multilayer welded joints. Seam cracks have a crystallite character and occur near the fusion line. Measurements of electrode potential of weld surfaces, showed that the potential is distributed uniformly in electric-slag welded joints, but drops sharply in the zone of thermal influence in joints made by automatic multilayer welding.

TITLE: Corrosion Resistance of Titanium Welds in Hydrochloric,  
Sulfuric and Nitric Acids (Korrozionnaya stoykost' svarnykh  
shvov titana v solyanoy, sernoy i azotnoy kislotakh)

PERIODICAL: Avtomaticheskaya Svarka, 1958, Nr 6, pp 42-50 (USSR)

ABSTRACT: Butt welds of technically pure "VT1" titanium of 3.0 mm thickness, welded under "AN-T1" flux with 2.5 mm titanium electrode rods, were tested in water solutions of sulfuric, hydrochloric, and 60% and 99% nitric acids. Tests in liquid and gaseous 99% HNO<sub>3</sub> were carried out with unloaded and with stressed specimens. Results are shown in tables and schematic drawings. The following conclusions are made: 1) titanium welds, tested under the aforementioned conditions, have the same corrosion resistance as the base metal; 2) commercial titanium and its weld joints are prone to corrosion cracks under tension in gaseous 99% HNO<sub>3</sub>. There are 6 tables, 3 photos, 2 graphs, 2 figures, and 16 references, 8 of which are Soviet, 6 English, 1 French, and 1 German.

PERIODICAL: Avtomaticheskaya svarka, 1958, Nr 9, pp 61-73 (USSR)

ABSTRACT: Application of "1Kh18N9T" steel for equipment used in the production of nitric acid requires welding processes producing joints that are resistant against corrosion and intercrystalline corrosion and which is similar to that of the base metal. For this purpose, natural corrosion tests of "1Kh18N9T" steel specimens welded with different electrodes under flux were carried out at the Chemical Combine imeni Stalin at Dimitrovgrad (Bulgaria). It was proved that seams welded with chromo-nickel-vanadium-niobium rods (OKh18N9FBS - EI649) and chromo-nickel-vanadium rods (OKh18N9F2S - EI606), have high corrosion and intercrystalline corrosion resistance under conditions of nitric acid production and that cold hardening by stretching, as well as by compression, increases

TITLE:

On Methods of Corrosion Testing of Welded Joints of  
Aluminum in Nitric Acid

PERIODICAL:

Avtomacheskaya svarka, 1959, Nr 8, pp 49-56 (USSR)

ABSTRACT:

The article deals with methods of testing corrosion resistance of welded joints of aluminum. The authors wish to ascertain the character of the action of nitric acid in relation to its concentration and temperature, and more precisely define the necessary and temperature, surface of samples and other experimental conditions in order to work out the most acceptable accelerated method of testing welded joints of aluminum in nitric acid. The authors open with a review and critique of other work in this field, including that of V.P. Batrakov [Ref 1], V.A. Savchenko [Ref 7], and F.B. Slomyanskaya and A.N. Krutikov [Ref 10], but they find a comparison difficult because the methods used varied. A method of testing welded joints of aluminum, worked

out by NIIKhJMMASh - boiling test samples in concentrated nitric acid for a long period of time (100-200 hrs) - is criticized as having poor reproducibility of results. The experiments described in this article were performed on type Al aluminum of the following composition: 0.20% Fe, 0.20% Si, < 0.01% Cu, the rest - aluminum. Sample dimensions were 70x30x4 mm; seam width was 12-14 mm. Nitric acid in concentrations of 10, 20, 30, 40, 50, 60, 70, 80% by wt. were used. Further particulars are contained in the text. The following conclusions were reached on the basis of the experiments: 1) the highest rate of corrosion was attained using 30% HNO<sub>3</sub>; for accelerated corrosion testing it is recommended that boiling 50% HNO<sub>3</sub> be used; 2) corrosion speed in 50% HNO<sub>3</sub> was determined as a function of time (Fig 1); the curve of this function levels out 2 hours after the start of the test; 3) tests in 50% HNO<sub>3</sub> guarantee a higher reproducibility of results in comparison with tests in concentrated

Nitric Acid

SOV/125-59-8-6/18

acid; in addition the character of the corrosion damage is preserved. The condition of the surface of the samples was found to have a comparatively small effect on the rate of corrosion (Fig 3). Further tests were carried out for comparative evaluation of the corrosion resistance of welded joints; a) boiling samples in 98% HNO<sub>3</sub>, for 100 hours, and b) by the accelerated method, i.e. two-hour boiling in 50% HNO<sub>3</sub>. Samples with three types of welds were used. Samples were compared by weight in arriving at a criterion for corrosion resistance. Results are tabulated (Table 3). Results of the 100-hour test in 98.3% HNO<sub>3</sub> support known data to the effect that identical samples in the same acid and under similar testing conditions give poorly corresponding results. However, good reproducibility of results was obtained in the 2-hour tests with 50% HNO<sub>3</sub>. In addition, structure and defects in the seam show up better after the two-hour test. Weight criterion of the corrosion resistance should be supple-

Intercrystalline Corrosion Concentrated Along the Fusion Line in Weld Joints of Stabilized 18-18 Type Steels (Edge-Corrosion)

To prevent edge corrosion, it is necessary to raise the Ti content and the Nb+Ta content in stainless steel; to use low-carbon 18-18 type steels; not to arrange the seams close to each other, in order to prevent secondary heat effects on the seam-adjacent metal; to treat the welds by stabilizing annealing. TITLE: On the Problems of Accelerated Corrosion Tests of Welded  
Aluminum Joints in Nitric Acid

PERIODICAL: Avtomaticheskaya svarka, 1960, Nr 1, pp 74-78 (USSR)

ABSTRACT: In their previous work Ref 17 the authors showed that  
50% nitric acid can be used for the accelerated testing  
of aluminum welds for corrosion resistance. Boiling for  
two hours in such an acid concentration ensures better  
results than tests with concentrated nitric acid. The  
optimum sizes of test samples are determined and the  
accelerated test method is explained. The size of the  
samples can considerably influence the results of the  
tests. Table 1 and graphs 1 and 2 show test results de-  
pending on the size of samples. The latter were tested  
for two hours in boiling 50% nitric acid. Figure 3  
shows samples of different length after the tests.  
As the ratio of the area of the basic metal in the

Card 1/3

SOV/125-60-1-10/18

On the Problems of Accelerated Corrosion Tests of Welded Aluminum Joints in Nitric Acid

sample increases in relation to that of the weld, the mean rate of corrosive destruction gradually drops. To determine the influence of the size of the butt end surfaces on corrosion of the welded joint, different thicknesses of the latter were tested. The results of these tests are given in table 2. Experiments were made by putting samples straight into boiling acid, and by putting them into cold acid and then bringing it up to the boiling point. The average rate of corrosive destruction depending on these two conditions is shown in table 3. On the basis of investigations, the results of which are described in the previous work /Ref 17/ and in this article, and after consideration of the results of tests conducted at plants, an industrial test method was developed. It includes instructions for the preparation of samples, the tests themselves and the methods of evaluating results. The method has been tried at a number of

TITLE: Electrode Wire for Welding Low-Alloy Steel Ship Hulls in Carbon Dioxide

PERIODICAL: Avtomaticheskaya svarka, 1960, No. 12, pp. 75 - 78

TEXT: Welds made in CXF (SKH1) type ship hull steel by УОНН-13/45А (UONI-13/45A) electrodes in manual welding, as well as by СВ-08Г2С (Sv-08G2S) wire semi-automatically in CO<sub>2</sub> have a low corrosion resistance in sea water. The reason for this is a lower electro-chemical potential in weld metal than in base metal, i.e., the weld forms the anode in the couple. An addition of 0.7 - 1.0% chromium to weld metal raises the corrosion resistance. The Electric Welding Institute im. Ye O. Paton has developed a new electrode wire that is recommended for use and called СВ-08ХГС (Sv-08KhGS). Its chemical composition is: up to 0.10% C; 1.4 - 1.7% Mn; 0.60 - 0.85% Si; 0.8 - 1.1% Cr, maximum 0.3% Ni; and maximum 0.03% S and P (each). The experiments were carried out with powder wire of different compositions, made in a special machine by bending low-carbon steel tape into a pipe and filling the pipe simultaneously with powder. The filled pipe

A161/A030

Electrode Wire for Welding Low-Alloy Steel Ship Hulls in Carbon Dioxide

was pulled through a die to reduce diameter and compress the core. The composition of ship hull steel used in experiments, 10ХСНД (10KhSND) is: 0.09% C; 0.61% Mn; 0.80% Si; 0.89% Cr; 0.55% Ni; 0.40% Cu; max. 0.03% S and P (each). The mechanical properties of welds produced with all of the tried wires were satisfactory. There are 2 figures, 2 tables and 2 Soviet references.

TITLE: On the method of investigating the tendency of welded joints to caustic embrittlement

PERIODICAL: Avtomaticheskaya svarka, no. 4, 1961, 86 - 87

TEXT: Brief information is given on a new method of caustic embrittlement tests requiring no special tension devices. Formerly, the Institut elektrosvarki im. Ye. O. Patona (Electric Welding Institute im. Ye. O. Paton) employed test specimens consisting of ribs welded to plates, and then the plates joined by butt welding, and later horseshoe-shaped specimens, or specimens loaded with a special device. Reference is made also to a recommendation of G. L. Shvarts and M. M. Kristal' to use a specimen 100 by 20 by  $\delta$  (mm) in size, cut from welded plate with removed projections and loaded by the application of a bending or stretching force. The authors have used a method requiring no application of devices for the loading. Detailed information on the new technique will be published later in "Avtomaticheskaya svarka". The method consists in using welded plates 500 x 400 x  $\delta$  (mm) in size and holding them in a boiling solution of 45% calcium nitrate and ✓

TITLE: Improving the corrosion resistance of low-carbon and low-alloy steel  
welds in an alkaline medium

PERIODICAL: Avtomaticheskaya svarka, no. 5, 1962, 36-43

TEXT: Since equipment used in the aluminum industry has to be frequently re-  
paired because of caustic embrittlement of low-carbon and low-alloy steel, and  
since alternative steels cost too much, the effect of stress-relieving on the  
resistance of low-alloy steel welds to caustic embrittlement was studied, using  
a method described by T.W. Green and A.A. Holzbaur ("The Welding Journal", No. 3,  
1946). The experimental equipment comprised a carriage with 4 gas burners pro-  
ducing a 120 mm-wide flame, and a water-cooling device 150 mm behind the flame.  
Five steel grades were tested. Calcium and ammonium nitrate solutions were  
used for corrosion tests. The electrode potential in specimens was measured.  
The experimental results show that the best ratio between Mn and C in the base

Improving the corrosion resistance of low....

metal was 1.7 : 3.0, and the highest potential was found in the 14 $\Gamma$  2 (14G2) steel - 61 mv before heat treatment, and 30 mv after. The anode zone was always revealed directly at the welds and appears to be the result of stress concentration. It is presumed that caustic embrittlement of low-carbon steel in strong alkali solutions begins with the destruction of the protective surface film, and this process is most intensive in metal at welded joints, where the anode potential is highest, but weld defects such as pin holes, slag inclusions, or spills also cause stress concentration and anode potential. Conclusions: (1) Thermo-mechanical treatment considerably improved the resistance of low-carbon and low-alloy steels to caustic embrittlement; (2) welds in 19 $\Gamma$  (19G), M 16C (M16S) and C $\Gamma$ .3 (St.3) steels have better resistance to caustic embrittlement than M (M) and 14 $\Gamma$  2 (14G2) steels; (3) the result of electrode potential measurements show that residual welding stresses intensify the anode processes in the weakness zone. There are 7 figures and 3 tables.

chromium-nickel steel of 21-5 type

SOURCE: Avtomaticheskaya svarka, no. 12, 1964, 30-37

TOPIC/TAGS: welding compound, ferritic austenitic steel, chromium nickel  
steel, electrochemical property, steel, macrocell, steel welding

ABSTRACT: The electrochemical properties of the weld compounds in steels  
were investigated, and it was found that they depend on the chemical composition  
of the welded seam, the grain size, and the steel properties resulting from the  
welding temperature, aggressiveness of the medium, and some other factors. In  
the boiling solution of 40% nitric acid, macrocells consisting of the base metal-  
seam and base metal-zone of thermal influence may be formed. If the joint dif-  
fers little from the base metal, the corrosion resistance is determined by the

TITLE: Corrosion resistance of weld joints of low-carbon steel type OOKh25N20

SOURCE: Avtomaticheskaya svarka, no. 11, 1964, 93-94

TOPIC TAGS: corrosion resistance, metal welding, nitric acid, steel, weld heat treatment, corrosion resistant, austenitic steel

ABSTRACT: Chromium-nickel austenitic steel type 1Kh18N9T and aluminum type AOO are used in equipment designed for the manufacture of concentrated nitric acid.

By following the optimum welding technology and techniques for joining type 1Kh18N9T steel the welds are stable to nitric acid at concentrations of up to 80% and temperatures of 70°C. At higher acid concentrations or higher temperatures the steel loses its corrosion resistance and weld joints frequently undergo extensive crack-type corrosion.

Attempts were made to use type KI654 steel for work under the indicated

Cond 1/6

L 33544-65

ACCESSION NR: AP5009176

conditions. However, weld joints of the steel tend to pitting, which reaches a depth of 3 mm/year.

Low-carbon austenitic steel's type 00Kh15N20 can be used for work with oxidizing media. The maximum decrease in the carbon of the steel must provide the necessary corrosion resistance for the steel and its weld joints under the indicated conditions.

Four samples of extremely low-carbon vacuum-thermal ferrochromium steel were prepared in induction furnaces at the Yuzhnorubnyy Metallurgical Plant and the Dneprospetstal' Plant. The chemical content of the steels is shown in Table 1.

After the steel was poured into ingots it was rolled into sheet billets. Welding was done by argon arc with a tungsten electrode. The welds were tested for corrosion resistance in a 65% solution of HNO<sub>3</sub> for 144 hours (solution replaced after 48 hours) and for 100 hours in a 98% solution of boiling HNO<sub>3</sub>. The results of the tests are shown in Table 2. For purposes of comparison, results are shown in the table of tests made on weld joints of type EI417 steel (0.11% C, 23.3% Cr, 20.4% Ni, 0.22% Si, 0.67% Mn, 0.013% S, 0.037% P). The samples were compared under the same conditions as the test steels.

The tested weld samples M, P, and Sh did not change in external appearance, but the surfaces of F-steel samples exhibited extensive corrosion.

Card 2/6

L 33544-65

ACCESSION NR: AF5009176

Welds of E1417 steel samples exhibited the greatest corrosion attack. The high carbon content invited extreme corrosion. It is interesting to note that the stability of type E1417 steel to an oxidizing medium such as a 65% solution of  $HNO_3$  increased considerably after cold working. The unaffected portions of the steel deformed during stamping were distinctly evident.

Microstudy of the samples after corrosion tests revealed that welds of M, R, and Sh steels do not tend to crack or intercrystalline corrosion. Weld joints of E1417 steel typically exhibit intercrystalline corrosion. 16

A decrease in the carbon content of the test steels, along with increasing their corrosion resistance to oxidizing media should also increase their corrosion resistance under stress. Our experiments confirmed this assumption. The sample steels Sh and P were tested for tendencies to stress corrosion in boiling 42% magnesium chloride. The tests were conducted on samples specially stressed to 90% of the yield strength. The results of these investigations are shown in Table 3.

TITLE: Corrosion tests of welded joints of 00Kh25N20 steel in nitric acid

SOURCE: Avtometicheskaya svarka, no. 6, 1965, 77

TOPIC TAGS: stainless steel, austenitic stainless steel, intercrystalline corrosion susceptibility, knife corrosion susceptibility, low carbon stainless steel/00Kh25N20 steel, 1Kh18N9T steel

ABSTRACT: Heat-treated (650°C for 2 hr) and untreated TIG-welded joints of 00Kh25N20 steel containing 0.018, 0.030, 0.045, or 0.055% C were tested for corrosion in nitric acid. Some specimens were completely submerged in 54–56% nitric acid at 100–105°C for 2445 hr. Other specimens were placed in the vapor of 64–65% nitric acid at 120–125°C for 3154 hr. For comparison, welds of 1Kh18N9T [AISI 321] steel were tested under identical conditions. The submerged 25-20 type steel did not change its appearance and exhibited no susceptibility to intercrystalline or knife corrosion. The corrosion rate varied from 0.01 to 0.04 g/m<sup>2</sup>·hr and was prac-

Card 1/2

L-56003-65  
ACCESSION NR: AP5016022

tically twice as high for heat-treated specimens ( $0.02-0.10 \text{ g/m}^2 \text{ hr}$ ). The welds of 1Kh18N9T steel were susceptible to knife corrosion. After testing in the gas phase, the steels containing less than 0.03% C preserved their appearance, but the surface of all other steel was corroded, particularly steel with 0.055% C and 1Kh18N9T steel. In tests in the vapor phase, the corrosion rate varied from 0.06 to  $0.10 \text{ g/m}^2 \text{ hr}$ :  $2.37 \text{ g/m}^2 \text{ hr}$  for steel containing 0.055% C and  $1.12 \text{ g/m}^2 \text{ hr}$  for 1Kh18N9T steel. Thus, the test under industrial conditions showed that welds of low-carbon austenitic steels of the 00Kh25N20-type containing less than 0.03% C are impervious to intercrysalline and knife corrosion in reactive and 65% nitric acid. TITLE: Filler-wire for argon-shielded arc welding of aluminum. Class 49, No. 182487  
[announced by the Electric Welding Institute im. Ye. O. Paton (Institut elektrosvarki)]

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 11, 1966, 128

TOPIC TAGS: welding, aluminum ~~welding~~, arc welding, argon, ~~shielded arc welding~~,  
welding wire, aluminum wire, ~~chromium containing wire~~, ~~zirconium containing wire~~  
~~corrosion resistance, chromium containing alloy, zirconium containing alloy~~

ABSTRACT: This Author Certificate introduces a filler-wire for argon-shielded arc  
welding of aluminum. To improve the weld corrosion resistance, the wire contains  
0.8—1.2% chromium and 0.7—1.2% zirconium. [ND]

TITLE: Corrosion resistance of steel with low nickel content in aggressive media 65

SOURCE: Metallovedeniye i termicheskaya obrabotka metallov, no. 2, 1966, 29-32 63

TOPIC TAGS: corrosion resistant alloy, stainless steel, chromium steel alloy, nickel containing alloy, molybdenum containing alloy 14 27 13

ABSTRACT: The effect of the chemical composition of stainless steel with low Ni content upon its corrosion resistance has been studied. The investigated steels were: OKh21N3T, OKh21N5T, OKh21N6M2T (I), Khl4G14N3T, and Khl7AGl4. Corrosive media selected were: 0.5N iron chloride solution, 3% solution of sodium chloride, 20% nitric acid, and sea water. Steel I, which contains 21% Cr, 6% Ni, and 2% Mo, was found to be most resistant to pitting under the described conditions. In general, it was established that resistance of heterogeneous ferrito-austenitic stainless steel to pitting is secured by an increase in Cr content and the presence of Mo.

2100 saturation tests were performed in various population groups in 1950 - 54. Saturation is lowest during February - May, and reaches a high level in the summer months, to decrease again in October. The hyposaturation of early spring is more marked and lasts longer in the northern mountainous regions than in the southern plains. Exceptions were seen in some places where potatoes and vegetables were abundant even in winter.

867. THE POSSIBLE ROLE OF STRUMIGENIC ALIMENTARY FACTORS IN THE AETIOLOGY OF ENDEMIC GOITRE IN SLOVAKIA - Studio sul possibile ruolo di fattori strumigeni alimentari nella eziologia del gozzo endemico in Slovacchia - Langer P., Sedlák J., Michajlovskii N., Stukovský R. and Pôdoba J. Ist. di Endocrinol., Acad. Slovacca delle Sci., Bratislava - ARCH. SCI. MED. 1958, 105/3 (257-266) Tables 5

A review is given of the various studies which have been made on the subject; it is demonstrated that some goitrogenic foodstuffs, especially those belonging to the family of the Brassicaceae, contain a considerable quantity of thiocyanates, so that the concentration of thiocyanates in the serum and the urine may be taken, to a certain extent, as an index of the amount of these foodstuffs ingested. These examinations are suitable for application to large groups of the population. Experimental studies in animals have revealed the goitrogenic properties of some local foods (vegetables, milk), which constitute a substantial part of the diet of the population. The results have shown that the goitrogenic potency of some vegetable foods depends on the presence of several sulphurated substances; their goitrogenic activities may therefore change with the content of these substances, which in its turn depends on the sulphur uptake.

"Some Peculiarities of Mental Development in Mongoloid Children"  
Prague, Casopis Lekaru Ceskych, Vol 102, No 4, 25 Jan 65, pp 100-105.

Abstract [Author's English summary]: The author deals with two problems  
of the so-called mongolism (Down's disease): 1. The degree of weak-minded-  
ness which occurs most frequently, 2. The specificity of the mental con-  
dition. Results in 70 children, aged from 4 to 16 years, showed that  
mongolism calls forth mostly a medium, and only in a lesser proportion  
severe or slight weak-mindedness. The author compared further 48 mongol-  
oid children with the same number of weak-minded non-mongoloid (with  
the use of pair method) and he found that the mongoloids show a stati-  
istically significant difference in disturbances of pronunciation and in  
social adaptability. Psychological examination methods were used. The  
results were statistically verified. [15 references, about half Eastern].
