TITLE: Search for anomalous hydrogen
SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 2, 1965,
389-392

TOPIC TAGS: hydrogen, deuterium, isotope, mass spectrometry/ MI 1311-04

ABSTRACT: An attempt was made to detect with the aid of a mass spectrometer elementary particles of mass greater than that of the proton. The MI 1311-04 mass spectrometer was subjected for this purpose to additional tests, to ascertain its maximum sensitivity and best resolution. By using an electron multiplier as both ion collector and first amplification stage, ion currents as low as 10^{-18} amp could be measured. In a vacuum of 2×10^{-7} mm Hg and at a background current of 2×10^{-18} amp, the resolution of the mass spectrometer at 5% mass-spectrum line intensity was found to be 500. After establishing the exact characteristics of the instrument, the authors undertook a search for anomalous stable hydrogen in atmospheric air, hydrogen, and deuterium. The results have established that if the mass of the wild hydrogen is larger than the mass of deuterium, then its concentration in the earth's atmosphere can be less than 1.5×10^{-12} , and if the mass

Card 1/2

09011078

L 27870-66

ACCESSION NR: AP5021097

of the wild hydrogen lies between that of ordinary hydrogen and deuterium, its maximum concentration should range from 1×10^{-8} to 1.5×10^{-12} . The lines corresponding to mass-5 in concentrated water, which might be ascribed to anomalous hydrogen, are shown to be due to HD_2^+ ions. It is recommended that earlier mass spectrograms be reviewed to search for lines which at that time were not identified with definite masses. "The authors thank L. B. Okun' for providing the initiative for this work, B. V. Ershler, B. Z. Torlin, and R. L. Serdyuk for useful discussions, and A. A. Belonozhenko for help with the measurements." 7149. Relations between the magnetic characteristics of macroheterogeneous magnetically-hard systems. ALTMAN, A. B., KAZARNOVSKII, L. Sh., AND MEMELOV, V. L. J. Tech. Phys., USSR, 19, 560-6 (May, 1949) In Russian.--The investigation was connected with the Fe-Ni-Al alloy permanent magnets produced by powder metallurgy. Systems of this kind, consisting of (1) a magnetically hard and a non-magnetic phase, (2) a hard and soft phase, (3) two different hard phases, were investigated. Remanent flux density B_r and coercive force H_c were measured as functions of the phase composition (quantity ratio of phases). It was found that the increase of the concentration of the non-magnetic phase, while reducing the remanent magnetism, does not alter the coercive force, whereas in the hard-soft mixed system the increase of the soft phase reduces both B_r and H_c . A direct proportionality between phase-relation and B_r was found to exist in the mixture of 2 hard materials; the coercive force decreases with the increasing content of the phase of lower H_c , but does not follow a linear law. AUTHORS: Gladyshev, P.A. and Memelov, V.L.

TITLE: Production and Properties of Cermet Iron-Nickel-Aluminium¹
Magnets²

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh nauk, Metallurgiya i toplivo, 1959, Nr 4, pp 106-110 (USSR)

ABSTRACT: The authors survey briefly the advantages and disadvantages of powder metallurgy⁴ relative to casting for making iron-nickel-aluminium magnets. They give a brief account of the mixing of the powder components, their properties, pressing and sintering (including the use of various protective atmospheres) and the heat treatment of the magnets. Fig 1 shows microstructures of alnico-alloy cermet and cast magnets; the greater porosity of the former being evident. Electron-microscopic and X-ray investigations were carried out with the participation of F.B.Nikishova and A.A.Katsnel'son. The electron-microscopic work showed the similarity of cermet and cast magnet structures and the effect of 2 hours tempering at 850°C on the grain size of the precipitating phase (Fig 2 shows structures before and after the tempering). No difficulties in preparing oxide replicas of the surfaces were encountered. X-ray analysis

Production and Properties of Cermet Iron-Nickel-Aluminium Magnets

(with powder having particle diameters under 0.15 mm) showed that the cermet and cast magnets have the same compositions and lattice parameters. Fig 3 gives powder diagrams for the two types and for a mixture of the initial powders. Increasing titanium content to 1% in the cermet magnet caused an increase in the lattice constants; with 5% Ti, lines of two cubic body-centred phases appear. Similar changes were observed on specimens after thermo-magnetic treatment but the diffuse nature of the lines prevented exact determination of the changes. Tests at NIIEP showed that cermet magnets are as stable as cast ones. Fig 4 gives demagnetization and magnetic-energy curves for various cermet-alloy magnets; compared with cast magnets their coercive force is equal and their residual magnetic-energy induction is 10 to 20% less. The authors state that supply of cermet magnets is not keeping pace with demand and suggest that they are best used on the mass-production scale in electrical instruments and small machines and also in the construction of new instruments: cermet magnets are particularly advantageous for small magnets of complicated shape. Their comparative ✓

TITLE: Study of Commutator Bars and Slip Rings Made From
Powders

PERIODICAL: Vestnik elektropromyshlennosti, 1960, No.9, pp.1-5

TEXT. Copper commutator bars and slip rings were made by pressing from the powder, sintering in a protective atmosphere and pressing in a die to give increased strength and more accurate dimensions. Copper-iron alloys and copper-iron bimetal were also made in this way. In its specific electrical resistance, strength and coefficient of linear expansion, copper made by this method was practically the same as that made by the usual rolling process. Table 1 shows the comparison. The rolled copper was somewhat harder (at 20°C). The properties of cermet copper-iron alloy changed in an additive way with increase in iron content. The density increased and the specific resistance and hardness

Card 1/2

Study of Commutator Bars and Slip Rings Made From Powders

decreased. The tensile strength was practically independent of composition. The coefficient of linear expansion of copper-iron bimetals was similar to that of steel, a fact which offers constructional advantages. With increase in temperature, the tensile strength and hardness of metallurgical copper, and of cermets of copper and copper-50% iron alloys all decreased. The biggest decrease was observed in metallurgical copper. Microstructures of cermet copper, copper-50% iron and copper-iron bimetals are shown. The cermet copper-iron consists of a mixture of copper and iron particles. In the bimetal, the good bond between the iron and copper can be seen. Commutator bars made by powder metallurgy were tested in starter motors. After 50000 cycles, the brush wear was 3 to 4.5 mm, the wear on the copper and the copper-iron bars was 0.1 mm, compared with 0.5 mm for normal copper. Copper-iron bimetals also gave good results. There are 2 figures and 3 tables.

TITLE: Investigation of the sintering process of Cu-Sn-C powdered-metal alloy

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 7, 1962, 47, abstract 7G329 ("Poroshk. metallurgiya", no. 6, 44 - 54; English summary)

TEXT: The change of properties (density ρ , hardness δ_s) was studied in the process of sintering the 90% Cu - 9% Sn - 1% C alloy whose initial components were taken both in the form of Cu-Sn and Cu-Sn-C alloys and in the form of Cu, Sn and C powders. Also the results are given of dilatometric, microdurometric and microscopic analyses which helped to establish the laws of homogenization, formation and disappearance of liquid phase. The best properties were found with the samples prepared from alloy powders.

SOURCE: Zavodskaya laboratoriya, v. 31, no. 12, 1965, 1528-1530

TOPIC TAGS: friction coefficient, friction, solid mechanics, abrasive, solid mechanical property, physics laboratory instrument, vacuum

ABSTRACT: A device (see fig. 1) was developed for continuous measuring of friction coefficient and temperature (150-500°C) of samples of abrasive materials during their friction under vacuum (10^{-7} mm Hg), in air and other media. The friction coefficient f (a function of the deflection angle α) is determined from the formula

$$f = LF/P \cdot r$$

where L is a lever of the pivot axis, F is the weight of the calibration load, P is the load applied and r is the friction radius.

TITLE: Dependence between total and surface porosity of sintered materials Cu--Sn--C

SOURCE: Poroshkovaya metallurgiya, no. 1, 1966, 41-45

27 27 27

TOPIC TAGS: copper, tin, carbon, graphite, powder metal compaction, powder metal sintering, **POROSITY, SINTERED ALLOY**

ABSTRACT: The effect of sintering temperature and pressure on the ratio of total (P_T) to surface porosity (P_0) of bronzographite (90% Cu, 9% Sn, 1% C) was investigated. The total porosity was determined by means of the formula

$$P_T = \frac{\gamma_0 - \gamma_1}{\gamma_0} \cdot 100, .$$

where P_T is the total porosity and γ_0 and γ_1 are the densities of nonporous and porous bronzographite respectively. The surface porosity was estimated from oil absorption data according to the formula

$$M = \frac{G_2 - G_1}{\gamma_w \cdot V} \cdot 100, .$$

TITLE: Mass spectrometric determination of very small amounts of boron in certain materials

SOURCE: Atomnaya energiya, v. 16, no. 5, 1964, 423-426

TOPIC TAGS: boron determination, boron mass spectrometry, isotopic dilution method, analytical chemistry, boron, mass spectrometry

ABSTRACT: The method of isotopic dilution suggested by G. Morrison and R. Rupp (Analyt. Chem. 6, (1957), 892) was used for the determination of small amounts of boron of the order of 10^{-7} gm in glass, quartz, and silicon. The sample was dissolved (or fused) in sodium hydroxide, internal standard was added which consisted of a known amount of an almost pure boron isotope (e.i. B^{10}), borax was then separated electrolytically, and placed on the filament of the mass spectrometer. The purpose of the pure isotope addition is to render harmless the boron losses during the chemical manipulations, as the determination depends only on the ratio of the spectrometric maxima of $Na_2B^{10}O_2$ to $Na_2B^{11}O_2$ and the comparison with the

Spottiness of silica brick. T. V. Memonova and L. M. Zilberfarb. *Ogneupory* 5, 617-1644 (1967).—Silica brick made from white quartzite uncolored by Fe oxides is white regardless of the CaO content. A 1% CaO content leads to the formation of pseudowollastonite yellow spots. The tridymitization is very small regardless of CaO content. Silica brick from ordinary quartzite contg. Fe oxides has, when 1% of CaO is added, a light yellow color with dark yellow spots. The addn. of 2-3% CaO gives a dark yellow and spotty coloring and a considerable content of pseudowollastonite and Ca ferrite. In the presence of the latter 2 substances the tridymitization is worse; this is characteristic of dark yellow ware. After repeated burning dark yellow ware changes to light yellow, sometimes with small dark yellow spots owing to a nearly complete disappearance of pseudowollastonite and Ca ferrite. The tridymite content increases. Spotty ware attains a homogeneous light yellow color, pseudowollastonite and Ca ferrite disappear, and tridymitization improves. Light yellow ware does not change color; the tridymitization increases. E. B. Stefanowsky

Title : Temperature Dependence of the Degree of Inversion of Mixed Ferrites

Orig Pub : Fiz. metallov i metallovedeniye, 1955, 1, No 3, 410-416

Abstract : Mixed ferrites having a composition $A_cB_{1-c}O.Fe_2O_3$ are examined. The free energy F of the spinel lattice is found as a function of the temperature T , of the concentration c , and of the degree of inversion λ . The dependence of λ on T is obtained from the condition that F must be a minimum. For the case when the ion charges A and B are equal and only the A ions shift in the octahedral sites, the following expression is obtained

$$kT = -b_1 \frac{\lambda + b_2/b_1}{\ln(c-\lambda)(2-\lambda)/\lambda^2}$$

where b_1 and b_2 are constants independent of λ and c . The range of possible values of λ was studied as a function of the values of b_2 and of $|b_2|/b_1$. A prediction is made that at low temperatures there may exist a metastable phase, which is inverse if the stable phase is not inverse, and vice versa. The

TITLE: Calculation of the Cohesive Forces in Some Oxides of Transition Metals (Raschet sil svyazi v nekotorykh okislakh perekhodnykh metallov)

PERIODICAL: V sb.: Issled. po zharoprochn. splavam. Vol 2. Moscow, AN SSSR, 1957, pp 44-51

ABSTRACT: The cohesive energy (CE) of a crystal was determined by the use of the statistical theory of electron gas. The Thomas-Fermi equation was set up with due account for the energy exchange of the electrons. It is taken into consideration that the numbers of electrons with right and left rotation are not equal, and either variety is examined separately. A system was developed for the solution of the Thomas-Fermi equation, without accounting for the exchange, by expansion into series. The simplest version of the theory was applied to determine the CE of oxides of transition metals with spinel structure. An expression for the period of crystal lattice, a_0 , was developed from the condition of minimum CE. Experimental data show

Card 1/2

137-58-6-13091

Calculation of the Cohesive Forces in Some Oxides of Transition Metals

that an increase in concentration of atoms with high atomic number leads to a decrease in a_0 . An equation is adduced for the degree of conversion, λ , applicable to some types of spinels. The temperature dependencies of λ calculated for certain values of the constants correspond to the experimental values. Concurrence is received therein for values of constants that correspond to not purely ionic cohesive forces.

126-3-25/34

TITLE: Influence of the changes in the equilibrium degree of inversion with temperature on the thermal capacity of a spinel. (Vliyaniye izmeneniya ravnovesnoy stepeni obrashchennosti s temperaturoy na teployemkost' shpineley).

PERIODICAL: "Fizika Metallov i Metallovedeniye" (Physics of Metals and Metallurgy), 1957, Vol.4, No.3, pp. 544-545 (U.S.S.R.)

ABSTRACT: The degree of inversion λ is defined as the extent of distribution of type A-atoms of a binary AB alloy along the a- and b-nodes. The author considers the oscillations in a simple model of an ordering solid solution, a linear chain. Knowledge of the maximum frequency ω_m of this chain permits certain conclusions on the characteristic of the heat capacity, assuming that a similar dependence for ω_m is also valid in a three-dimensional lattice. The structure of the investigated mixed oxides, in which the ions of various types can interchange their location in the lattice, is in many respects similar to the structure of ordering metallic alloys where analogous rearrangements of the ions can take place. Since oxygen ions do not participate in these movements they need not be considered in investigating some properties of the spinel lattice. In this

Card 1/5

126-5-25/34

Influence of the changes in the equilibrium degree of inversion with temperature on the thermal capacity of a spinel. (Cont.)

case the theory of ordering alloys is applicable to such a lattice. However, it is necessary to consider that between the degree of the distant order η (expressing to what extent the a-nodes are occupied by A-atoms and the b-nodes are occupied by B-atoms of a binary AB alloy) and the degree of inversion λ (which is a measure of the distribution of the type A-atoms along the a- and b-nodes) the following relation is valid:

$$\lambda = (1 - c) (1 - \eta),$$

where $c (\neq 1)$ is the concentration of the type A-atoms. The existence of this relation is utilised for investigating the oscillations of the linear model of the mixed spinel lattice. The example of a unidimensional chain permits elucidation of a number of relations which are characteristic for a three-dimensional crystal. In an earlier paper (Dokl. Ak. Nauk, 1953, Vol.90, p.753), the linear chain was considered consisting of atoms of two types, which interact elastically, distributed along the nodes of a chain with any degree of the distant order η and any arbitrary concentration c . It is shown that for known approximations such a chain can be

Card 2/5

126-3-25/34

Influence of the changes in the equilibrium degree of inversion with temperature on the thermal capacity of a spinel. (Cont.)

considered as an ordered one consisting of real atoms. Applying this method to a chain in which the atoms of the mass M (oxygen) are located on the spot and the (metal) atoms with the masses m_1 and m_2 are distributed along the nodes of the chain with any arbitrary degree of inversion λ and any concentration c , it is possible to derive the relation for the maximum frequency of the degree of inversion which is expressed by eq.(2), p.545. According to Seitz, F. (2) and Fermi, E. (3) the heat capacity of a unidimensional model can, in the general case, be approximately represented by a sum of two components:

Card 3/5

$$C_V = 2NkD\left(\frac{kT}{\hbar\omega_m}\right) + 2Nk f_E\left(\frac{\hbar\omega_0}{kT}\right)$$

where D is a Debye function, f_E is the Einstein function. The first term of this equation E describes in the framework of the theory of the continuum, the heat capacity due to low frequency oscillations, whilst the second expresses the relations with optical oscillations which are characterised by the frequency ω_0 . Improving the theory by taking into

Influence of the changes in the equilibrium degree of inversion with temperature on the thermal capacity of a spinel. (Cont.)

consideration numerous optical frequencies is not justified in view of the fact that the above equation represents only a very rough approximation. By making the maximum frequency, determined according to eq.(2), p.545, identical with the Einstein and the Debay ones and considering the relation $\omega_m(\lambda)$, it is possible to elucidate within the framework of the assumed model the distribution of the ions in the chain on the heat capacity. According to earlier work of the author (same journal, 1955, Vol.1, p.410) the equilibrium degree of inversion entered in eq.(2) depends on the temperature and, therefore, it can be anticipated that for some spinels there will be deviations ΔC_v in the temperature characteristic of the heat capacity from that predicted by the eq.(2) for $\omega_{max} = \text{const.}$ For an equal dependence of the maximum frequency on the degree of inversion the normal and the inverted spinels have deflections ΔC_v of equal sign but at differing temperatures. The here obtained predictions on the deviations of the heat capacity could not be detected in principle in the only ferrite which, according to the knowledge of the author, has so far been investigated experimentally, i.e. the non-ferromagnetic
