TITLE: Investigation of the machinability of low-Carbon steels of the Fe-Mn, Fe-Mn-Cr, and Fe-Mn-Cr-N systems.

SOURCE: Akademiya nauk Gruzinskoy SSR. Institut metallurgii. Trudy, v. 11, 1961, 203-207.

TEXT: The paper describes an experimental investigation comprising a study of the machinability of low-C (C=0.1%) Mn, Cr-Mn, and Cr-Mn-N steels in conjunction with a general effort to make and study high-Mn stainless steels. The machinability criteria were based on the standard methods set forth in All-Union Standard (GOST) 2625-44. The test specimens specified in the Standard are rolled rods not less than 60-mm diam for longitudinal machining and not less than 150-mm diam for transverse turning; inasmuch as only cast specimens of smaller diam were available a slightly modified methodology was employed in which the machinability was determined by means of comprehensive data on longitudinal and transverse machining, the depth of drilling under a constant load, and various sawing methods. The basic criterion was the depth of a 2-mm diam hole drilled in 1 min. Following are the basic definitions of the 4 qualitative machinability groups: (1) "Nonmachinable" are

Card 1/2

Investigation of the machinability of low-Carbon . . . . S/808/61/011/000/006/006

those steels characterized by a mean drillhole depth of 1 mm and total resistance to sawing and turning with a high-speed steel cutter; (2) "difficult-to-machine" are those steels characterized by a mean drillhole depth of from 2 to 5 mm and by substantial resistance to sawing and turning (standard: Steel ЭЯ1Т [EYalT] ); (3) "readily machinable" are those steels characterized by a mean drillhole depth of 6 to 10 mm and ready sawability and turnability (standard: Steel 50); (4) "excellently machinable" are those steels characterized by a mean drillhole depth of more than 10 mm and easy sawability and turnability (standard: Calibrated steel 25). A total of 85 Mn, Cr-Mn, and Cr-Mn-N steels were tested. The results are tabulated and graphed. The overwhelming majority of the steels investigated of the 3 systems, containing from 0 to 30% Mn and Cr with 0.1% C, are characterized by good machinability, both in the cast and in the quenched state. In most of the steels investigated, a homogenization at 1,150°C and subsequent quench does not impair the machinability but, on the contrary, improves it appreciably. It is asserted that the opinion, widely prevailing throughout the literature, that low-C steels of the Fe-Mn-Cr and Fe-Mn-Cr-N systems are not readily machinable, requires correction and that the Fe-Mn, Fe-Mn-Cr, and Fe-Mn-Cr-N stainless nonmagnetic steels investigated are more readily machinable than standard Cr-Ni steels. There are 2 figures and 1 one-and-one-half-page table; no references.

TITLE: Ionization pulse gas analyzer/detector. Class 42, No. 177681 [announced by Tomsk Polytechnic Institute of the Order of the Workers' Red Banner (Tomskiy ordena trudovogo krasnogo znameni politekhnicheskly institut)]

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 1, 1966, 106

TOPIC TAGS: gas analyzer, gas composition analyzer, gas ionization

ABSTRACT: This Author Certificate presents an ionization pulse gas analyzer detector containing a chamber with two coaxial electrodes. An ionization source, e.g., an ~~alpha~~-emitter, is located inside the chamber. To increase the sensitivity of the detector to electronegative gases (e.g., oxygen in argon), the ionization source is located at the bottom of an annular slot in the insulating end cover of the chamber (see Fig. 1).

ABSTRACT: Drainage of land with a high ground water level can be  
carried out successfully by vertical drains. For this pur-  
pose pump wells are equally distributed over the entire are  
at a certain distance from one another, which can be determ  
ined by the condition of the minimal yearly expenditure of  
draining 1 ha of swamp area. The author evolves a number o  
formulas showing the advantage of vertical drainage for  
certain areas. With low costs for electric power, it is  
possible to have a greater lowering of the water level than  
can be obtained by filtration of the ground. The distance  
between the pumps is governed by the permeability of the

AUTHOR: Vasil'kov, B. S. (Moscow); ~~Minskyev, L. S.~~ (Moscow)

TITLE: On the stability of flat shells with double curvature on a rectangular surface

SOURCE: Inzhenernyy zhurnal, v. 4, no. 3, 1964, 566-570

TOPIC TAGS: flat shell, Gaussian curvature, instability, critical load, minimum load, local stability, stress function, trigonometric series, Galerkin method

ABSTRACT: On the basis of V. Z. Vlasov's (Obshchaya teoriya obolochek i yeys prilozheniya v tekhnike. Gostekhnizdat, 1949) theory of flat shells with linear arrangement, the stability of shells with positive Gaussian curvature was studied. Deflection at the moment instability sets in is represented by  $w = \sin(m\pi x/a) \sin(n\pi y/b)$  where the critical load is defined by means of a particular value of  $m$  and  $n$  for a minimum load. The equations of local stability are written

$$\frac{1}{Eh} \nabla^4 w + (k_1 \frac{\partial^2 w}{\partial x^2} + k_2 \frac{\partial^2 w}{\partial y^2}) = 0,$$

$$D \nabla^4 w - (k_1 \frac{\partial^2 w}{\partial x^2} + k_2 \frac{\partial^2 w}{\partial y^2}) + N_1^0 \frac{\partial^2 w}{\partial x^2} + 2N_2^0 \frac{\partial^2 w}{\partial x \partial y} + N_3^0 \frac{\partial^2 w}{\partial y^2} = 0,$$

Card 1/3

ACCESSION NR: APL043533

where  $\varphi$  - stress function,  $N_1^0, N_2^0, S^0$  - normal and shear loads.  $\varphi$  and  $v$  are represented as products of functions, or  $\varphi(x, y) = AU(x)Y(y), v(x, y) = BX(x)Y(y)$ , and the loads expanded in double trigonometric series, for example,

$$N_1^0 = \frac{16a^2}{\pi^2 b^2} \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \frac{1}{(k_2^2 + k_1^2 n^2)} \sin \frac{\pi m x}{a} \sin \frac{\pi n y}{b}$$

Galerkin's variational method is employed, which subsequently leads to an expression for the load  $q$  expressed by

$$q = \frac{\pi^2 E a^2 (k_2^2 + k_1^2) (m^2 \gamma^2 + n^2 \gamma^2) (m^2 - 0.25) (n^2 - 0.25)}{768 (1 - \mu^2) a b m^2 n^2 (m^2 + n^2 - 0.5)} + \frac{\pi^2 E a b^2 (k_2^2 + k_1^2) (k_2 m^2 \gamma^2 + k_1 n^2 \gamma^2) (m^2 - 0.25) (n^2 - 0.25)}{64 (m^2 \gamma^2 + n^2 \gamma^2) m^2 n^2 (m^2 + n^2 - 0.5)}$$

The critical load is then determined for two special cases: 1)  $n = 1, m^2 \gg 1$  or  $m = 1$  and  $n^2 \gg 1$ , and 2)  $m \geq 2, n \geq 2$ . The first gives for  $q_{cr}^*, \gamma^2 = 0.75 k_1 \gamma^2 (k_2 \gamma^2 + k_1 \gamma^2)$ , where  $\gamma^2 = \frac{64 \sqrt{3} (1 - \mu^2)}{\pi^2 E b^2}$ . The second case leads to similar results but at a higher value of  $q$  (critical) than the former case. Orig. art. has: 31 equations.

AUTHORS: Latsh, V. V., Minayev, N. G., Somin, B. Kh.

TITLE: X-Ray Study of the Phase Composition of Ni-Zn Ferrites by  
Using  $CoK_{\alpha}$  Radiation

PERIODICAL: Fizika tverdogo tela, 1960, Vol. 2, No. 7, pp. 1632-1642

TEXT: The use of the emission of an iron anticathode for analyzing the phase of Ni-Zn ferrites proved to be inadequate since it renders the determination of NiO or of the solid solution of ZnO in NiO difficult or impossible because the lines of NiO and the spinel coincide. If harder (monochromatized)  $Co-K_{\alpha}$  radiation is used, this disadvantage is not observed; the X-ray pictures show two additional intensive interference lines of NiO with the indices (133) and (420), and the Bragg angles  $69^{\circ}$  and  $74^{\circ}$ , respectively. An X-ray tube of the type  $\text{ECB-4}$  (BSV-4) (time of exposure 10 hours; 10 ma, 35 kv) was used for taking the Debye powder patterns. Mixed oxides with an NiO:ZnO ratio of 0.35 - 1.1 and an  $Fe_2O_3$  content of 45-55.0 mole% were studied. By means of  $Co-K_{\alpha}$  radiation, interference lines could also be observed at the following concentrations:

Card 1/3

X-Ray Study of the Phase Composition of Ni-Zn S/181/60/002/007/045/047/XX  
Ferrites by Using  $\text{CoK}_\alpha$  Radiation B006/B067

NiO (0.5 wt%), ZnO (2.0 wt%),  $\text{Fe}_2\text{O}_3$  (2.0 wt%). The results of the investigations are illustrated by means of X-ray diagrams, tables, and microstructural pictures, and they are summarized as follows: 1) With  $\text{Co-K}_\alpha$  radiation NiO or ZnO can be determined in Ni-Zn ferrites and NiO, respectively by means of interference lines. 2) During the ferritization process, in the case of stoichiometric composition, no formation of solid ZnO solutions in NiO was observed. The formation of Zn ferrite in the synthesis from oxides ceases at a temperature of  $900^\circ\text{C}$ , the ferritization of nickel ferrite ceases at  $1100^\circ\text{C}$ . 3) A rise of the annealing temperature of ferrite mixtures with a low content of iron oxide over  $900^\circ\text{C}$  leads to a substitution reaction between the excess NiO and the Zn ferrite which brings about a change in the ratio between divalent Ni and Zn ions in the ferrite lattice. 4) Zinc oxide and nickelous oxide form solid substitution solutions with conservation of the Ni-O crystal lattice; the lattice parameter practically increases linearly with increasing ZnO content (see Fig. 3 and Table 3). The solubility limit of ZnO and NiO amounts to about 50 wt% at an annealing temperature of  $1350^\circ\text{C}$ . If this temperature is reduced to  $900^\circ\text{C}$  the solubility limit of ZnO is reduced to  $\sim 30$  wt%. A change in the solubility of ZnO in NiO could not be observed on a further

Card 2/3

B006/B067

temperature increase; this is connected with the strong decrease of the diffusion rate. 5) In Ni-Zn ferrites with less than 50 mole% of  $\text{Fe}_2\text{O}_3$ , NiO and ZnO excesses exist which form solid solutions. The formation of a solid ZnO solution in NiO was observed after the termination of zinc ferritization. B. Ye. Levin is mentioned. There are 8 figures, 3 tables, and 11 references: 9 Soviet and 1 US.

PERIODICAL: Fizika tverdogo tela, 1960, Vol. 2, No. 9, pp. 2191 - 2198

TEXT: For the purpose of explaining the contradictory published data concerning the solubility of  $Fe_2O_3$  in ferrites, the authors carried out the following experiments: Ni-Zn  $\eta$  ferrites with a content of 50-95 mole%  $Fe_2O_3$  and an NiO/ZnO ratio of from 0.43 to 4.0 were synthesized from the oxides, were briquetted after the addition of polyvinyl alcohol as a binding agent, annealed for 4 h at 1000-1350°C, after which they were either slowly cooled (100°C/h) in a furnace or quenched with air or water. Besides, they were also slowly cooled under oxygen deficiency (0.7 to 0.35 torr). Fig. 1 shows the results obtained by chemical analysis: The quantity of  $Fe_2O_3$  converted into magnetite as a function of the  $Fe_2O_3$  content and the cooling conditions; Fig. 2 shows the quantity

of  $\text{Fe}_2\text{O}_3$  converted into magnetite as a function of the annealing temperature. The quenched samples were found to have the highest magnetite content. The  $\text{Fe}_2\text{O}_3$  excess dissociates to form magnetite, and together with the ferrite it forms solid solutions of iron-nickel-zinc ferrite of stoichiometric composition. When slowly cooled in air, the magnetite is oxidized to  $\gamma\text{-Fe}_2\text{O}_3$  or  $\alpha\text{-Fe}_2\text{O}_3$ . The latter separates as the second phase. Figs. 3-6 (microphotographs) confirm this process. The quenched samples form a homogeneous phase, while the slowly cooled samples have two phases because of the separation of hematite. X-ray analysis (Fig. 7) shows that the lattice constant of quenched samples approaches that of magnetite (8.38 kX), whereas  $\text{Fe}_2\text{O}_3$  formed by oxidation reduces the lattice constant (8.32 kX at 100 mole%  $\text{Fe}_2\text{O}_3$ ). Fig. 8 shows the temperature of the dissociation of  $\text{Fe}_2\text{O}_3$  to  $\text{Fe}_3\text{O}_4$ , as a function of the  $\text{Fe}_2\text{O}_3$  content. For pure  $\text{Fe}_2\text{O}_3$ , the dissociation temperature is  $1450^\circ\text{C}$ , and in the system

TITLE: The influence of nickel on the sinterability of pressed powders of tungsten and molybdenum

CITED SOURCE: Tr. Kuyby\*shevsk. aviats. in-t, vy\*p. 16, 1963, 141-148

TOPIC TAGS: powder metallurgy, nickel, tungsten, molybdenum, material strength, heat-treatment

TRANSLATION: Research was conducted on the influence of Ni on sintering in an atmosphere of H<sub>2</sub> and in vacuum Mo and W in a range of 1,100-2,000 degrees for Mo and 1,100-2,500 for W, with a nickel content of 0.01-10% by weight. Density (P), microstructure, microhardness, and the parameters of the crystal network of the first phase were studied. An increase in the density of the sintered Mo with an inclusion of 0.5-1% Ni takes place as low as 1,100 degrees. At 1,300 degrees, the porosity of the samples with the above nickel content amounts to 10%. At 1,500 degrees, the effectiveness of the influence of small inclusions of Nickel on the sinterability

Card 1/2

ACCESSION NR: AR4018314

of Mo decreases considerably. The curves of function P of sintered W with the nickel content has a maximum equal to a 0.25% nickel content. After sintering at 1,500 degrees, the W with an admixture of 0.25-0.5% nickel amounts to 5-7%. The inclusion of nickel also leads to an increase in the microhardness of W from 250 to 600 kg/sq cm, and the microhardness of Mo from 150 to 500 kg/sq cm. The liquifiability of nickel at 1,500 degrees is 0.3 atmospheric % in W and 1 atmospheric % in Mo. At sintering temperatures of 1,350 degrees for Mo, and 1,495 degrees for W, and a nickel content greater than 0.5% for Mo and 0.25% for W, an oozing out of the Nickel phase is observed, accompanied by a decrease in hardness of the samples during sintering in H<sub>2</sub>.

TITLE: Investigation of the Dependence of the Friction Force on the Real Area of Friction and the Normal Load (Issledovaniye zavisimosti sily treniya ot istinnoy ploshchadi treniya i normal'noy nagruzki)

PERIODICAL: Izvestiya Vysshikh Uchebnykh Zavedeniy, Fizika, 1959, Nr 1, pp 35-43 (USSR)

ABSTRACT: A great drawback of most of the work devoted to experimental study of the process of external friction lies in the fact that the experiments were carried out without knowing the magnitude of the real friction area which really does participate in the friction process. The friction theories prevailing at present are based on the incorrect concept that the real area of friction is the area of contact of the rubbing pairs. This complicates understanding the process of external friction and also complicates the physical interpretation of experimentally established facts. This relates particularly to the dependence of the coefficient of external friction on the normal load. In earlier work one of the authors of this paper (Refs 8-10) applied

Card 1/6

SOV/139-59-1-6/34

Investigation of the Dependence of the Friction Force on the Real Area of Friction and the Normal Load

the concept of V. D. Kuznetsov (Ref 1) and of Bowden and Tabor (Ref 12) on the physical nature of the process of external friction and attempted to justify the point of view that this process consists basically of plastic shear which proceeds inside relatively thin surface layers of the rubbing pairs. As a result of this, the real friction area is that along which the process of shear takes place during friction. This point of view follows directly from analysis of the basic types of interaction of solid surfaces which bring about external friction (Refs 8,9). To verify experimentally this concept, the friction was studied of a semi-spherical slide block made of hardened steel along freshly cut surfaces of the following metals: tin, lead, aluminium, copper, zinc, bronze, steels 45 and U12, iron, alloys EI437, VT2 etc. It was found that displacement of the slide block along a freshly cut surface of the specimen brings about the formation of a "stagnant" zone (build-up) and that the displacement of the slide is not effected by external

Card 2/6

SOV/139-59-1-6/34

Investigation of the Dependence of the Friction Force on the  
Real Area of Friction and the Normal Load

sliding along the surface of the specimen but by shifting (shear) along the internal boundary of this zone. Thus, in the case of pure metallic rubbing pairs, the friction does not consist in cutting off the molecular bridges occurring at the points of physical contact, as was suggested by Bowden, but by shear along the internal surface of the "stagnant" zone. On increasing the normal load  $N$  there will be an increase in the real area of friction  $S_c$  and of the friction force. Thereby, with increasing  $N$  the specific friction force  $f$  will remain practically unchanged and will equal approximately the shear strength of the material of the specimen (Ref 10); this indicates that the friction force is determined de facto by the friction surface and is almost independent of the normal pressure. Since this latter conclusion is considered of great importance, the authors studied the behaviour of the friction force under conditions such that the friction area remained practically unchanged in spite of the continuous increase in the normal load. These experiment

Card 3/6

SOV/139-59-1-6/34

Investigation of the Dependence of the Friction Force on the Real Area of Friction and the Normal Load

were carried out by means of a cutting tool with a limited friction area. In the experiments chips of a pre-determined thickness between 0.02 and 1.0-3.0 mm were planed off by means of a specially built cutting tool, a sketch of which is shown in Fig 3, p 38. This tool consisted of a high speed steel wedge with an angle of  $30^{\circ}$  at the apex and a facet with an angle of  $25^{\circ}$ , whereby the width of the facet varied between 0.2 and 1.0 mm. In Fig 5 the dependences are graphed of the horizontal and the vertical components of the planing force of brass as a function of the depth of cut. Fig 6 shows a typical curve of the dependence of the friction force on the normal force applied during planing of aluminium by means of the special cutting tool used in the experiments, which had a limited area of friction. In Fig 7 the dependence is graphed of the friction force on the normal force for iron, copper, brass, aluminium, lead and tin. It can be seen from the graphs, Fig 7, that qualitatively the picture is the same for all meta-

Card 4/6

SOV/139-59-1-6/34  
Investigation of the Dependence of the Friction Force on the  
Real Area of Friction and the Normal Load

It is concluded that the friction force is not directly dependent on the normal force but only indirectly, inasmuch as the normal force determines the size of the friction area. However, if the size of the friction area cannot change with the magnitude of the normal force, the friction force will no longer depend on the normal load. It can be seen from the data of Table 2 that the specific friction force does not depend on the width of the land and is approximately equal to the shear strength of the machined metal. The shear strength was determined by means of a press, a sketch of which is shown in Fig 9, p 42. The following conclusions are arrived at:

- 1) The process of external friction of pure metallic surfaces consists mainly of plastic shear taking place in the relatively thin surface layers of the rubbing pairs along areas, the magnitude of which is generally a function of the normal component of the load.
- 2) The main factor which determines the friction force is the real area of friction. The friction will be dependent on the normal force only as long as this normal force determines the size of the real area of friction. However,

SOV/139-59-1-6/34  
Investigation of the Dependence of the Friction Force on the  
Real Area of Friction and the Normal Load

if this area of friction cannot change as a result of changes in the normal load, the friction force will no longer be dependent on the normal load.  
3) The real area of friction is the area along which the process of shear develops during friction. If the real area of friction is correctly evaluated, the specific friction force will equal the shear strength of the weaker member of the rubbing pair in which the shear is localised.

TITLE: Effect of sealed closures of piston rings on the starting qualities of  
diesels

SOURCE: Avtomobil'naya promyshlennost', no. 1, 1967, 14-16

TOPIC TAGS: temperature dependence, temperature measurement, piston engine, diesel  
engine, engine component, ENGINE PISTON, ENGINE STARTER SYSTEM

ABSTRACT: The equation for compressed gas in a cylinder (with consideration of the  
leakage through the piston rings) is given as

$$T_c = T_a \left[ \left( 1 - \frac{\Delta G}{G_a} \right) \right]^{n_1 - 1}$$

where  $n_1$  is the average exponent of the compression curve; T and G are the temperature  
and weight. The subscripts a and c refer to the start and the end of the compression;

Card 1/3

ACC NR: AP7003518

Fig. 1. Air temperature at the compression ring vs number of engine rpm: 1 - three-component ring; 2 - ring with soldered closure; 3 - standard ring

$\Delta G = G_a - G_c$  is the gas loss during compression. With  $V$  representing the volume of gas,  $\mathcal{E} = \frac{V_a}{V_c}$  is the geometrical degree of the engine compression. To determine the

rpm effect on  $\frac{\Delta G}{G_a}$  and  $T_c$ , tests were conducted on a single-cylinder assembly with

a cylinder diameter of 150 mm and an effective  $\mathcal{E} = 12.8$ . The piston was driven by a Pendel-dynamo, and the gas leaking past the piston rings was collected from the crankcase and measured by a rotameter. The temperature was measured by a tungsten resistance thermometer replacing an injector in the head. Three types of piston rings were tested: a) the standard type with a 0.6-mm gap in the closure; b) a

Card 2/3

ACC NR: AP7003518

similar ring with the gap sealed by tin solder; c) a compounded ring of three overlapping layers with no gap. Where the leakage was small,  $\frac{\Delta G}{G_a}$  vs rpm was hyper-

bolic. For standard rings  $\frac{\Delta G}{G_a} = \frac{16}{n}$ , and for the soldered gap it is  $\frac{8.2}{n}$ . The

temperature dependence is shown in Fig. 1. Rings made by German and American firms have complex tongue closure sections which effectively seal and also compensate for small irregularities in the cylinder shape. Orig. art. has: 6 figures and 5 formulas.

Combined action on muscle of adenosine triphosphate, acetylcholine, and potassium, calcium, and magnesium ions. Eug. B. Babitski and P. P. Minayev (Inst. Biol. Chem., Acad. Med., Moscow). *Nature* 158, 238(1946). Adenosine triphosphate did not produce contraction of the m. rectus abdominis of the frog and led to small contractile response of the leech muscle, at the concns. used. After one application of the adenosine triphosphate soln. the frog and leech muscles react to solns. of acetylcholine with contractions of increased intensity. It follows that adenosine triphosphate sensitizes the muscle to acetylcholine. The increased concn. of K ions leads to a markedly increased reaction to acetylcholine of muscles subjected to the action of adenosine triphosphate. Contraction of myosin threads produced by adenosine triphosphate in the presence of KCl is inhibited by Ca ions and increased by K and Mg ions. When the concn. of Ca ions is increased adenosine triphosphate does not cause contraction of the dorsal muscle of the leech. Both in the frog muscle and in that of the leech adenosine triphosphate produces no contraction in Ringer soln. with increased content of Ca, and leads to a persistent decrease of the contractile response to acetylcholine.

Phosphocreatine and Adenylatephosphate (ATP) changes in brain cortex after electric convulsions. P. F. Minayev and T. P. Kurokhitina (Inst. Biol. and Med. Chem., Acad. Med. Sci. U.S.S.R., Moscow). *Ukrain. Biokhim. Zhur.* 21, 359-62 (1949) (in Russian).—The content of phosphocreatine (I) and of ATP (II) decreases sharply after convulsions and before a 2nd stimulus is effective, excitability of the cortical motor zone decreasing sharply at the same time; 30 min. after termination of convulsions, the contents of I and of II in the cortex return to normal, by which time excitability of the cortex has been considerably restored. Trephination of the dog skull was carried out under morphine-ether-chloroform or ether-chloroform; 30 min. after inclusion of the dura mater, excitability of the cortical motor zone was detd. by a constant current from Ag electrodes of a chronoaximeter, and was estd. by contraction of the hind paw extensor muscles. Having detd. excitability, a portion of the cortex was excised from 1 control lobe by a surgical spoon chilled in liquid air and the sample frozen in liquid air, no more than 2-3 sec. lapsing from moment of sampling to immersion in liquid air. Five min. after the excision, convulsions were produced by elec. current, 1 electrode on the lower lip, the second on the neck muscles. Duration of the irritation was 2-3 sec., with 1-min. intervals between convulsions. It was not possible to obtain more than 5-12 seizures in a row, the last attacks being short and weak. Convulsions having ceased, a portion of cortex from the 2nd lobe was similarly excd., frozen, and the excitability detd. every 5-10 min.; 30 min. after termination of convulsions, 1 more portion of cortex was excised and frozen. Each of the 3 portions of cortex were ground to a powder, while frozen and cooled 8%  $\text{CCl}_3\text{COOH}$  was added (1:10). The following P compds. were detd. in the filtrate: (1) inorg. P, after pptn. with  $\text{Mg}$  mixt., (2) some inorg. P + phosphocreatine P, (3) P after 10-min. hydrolysis in 1N HCl at 100°. P was detd. colorimetrically according to Fiske and Subbarow in a step photometer.

liquid or with glutaminic acid and glucose. Finds  
both combinations more effective than ATP alone.  
Mechanism of effect is normalization of oxidation  
processes in body tissue creating conditions favor-  
able for removal of ammonia from cen nervous system.

Changes in the central nervous system during local action of X-rays. P. F. Minayev. *Sov. Obshchest. Biol.* 15, 401-12 (1954).—Exptl. animals were exposed to various doses of Röntgen rays, and local and general effects of the rays on responses to conditioned reflexes, histology of the brain, as well as certain biochemical reactions of exposed brain tissue were examd. Responses to conditioned reflexes were altered, depending on the dose of the rays administered and depending on the site of the brain which was exposed to the irradiation. The extent of damage to the brain cells depended on the dose (necrosis), and the functional activity of the brain could be selectively altered by the dose of irradiation and judicious choice of the site of application. After Röntgen irradiation to the brain the extent of aerobic oxidation of glucose was decreased, accompanied by an increase in the anaerobic oxidation of glucose with the production of lactic acid. This occurred even during administration of therapeutic doses of the ray (500 r.). The process of oxidative phosphorylation was also altered in brain tissue by the irradiation, while exposure of brain to either small or large doses of Röntgen rays had no effect on content. J. A. Stekcl.

Title : The decisive role of the nervous system in the ethiology and pathogenesis of traumatic shock.

Periodical : Dok. AN SSSR 99/5, 865-868, Dec 11, 1954

Abstract : Experiments were carried out on dogs and cats to determine the role of the nervous system in the ethiology and pathogenesis of traumatic shock. According to toxic theory the decisive factor in the ethiology of traumatic shock is the accumulation of toxic decomposition products in the organism. According to the plasm-blood loss theory the basic cause for traumatic shock is the loss of plasma and blood by the organism. Both theories taken individually do not however explain the complexity of the process which develops in the organism during traumatic shock. Five USSR references (1953). Diagrams.

 TITLE The Influence Exercised by the Local Irradiation of the Nervous System with X-Rays on the Composition of Peripheral Blood.  
 PERIODICAL Dokl.Akad.Nauk, 109, fasc.2, 303-304 (1956)  
 Publ. 7 / 1956 reviewed 9 / 1956

The cerebral hemispheres and the cerebellum of white Leghorn hens were irradiated by the directed X-rays (total dose 7000-9000 Roentgen) of a tube of 180 kV, 10 millampere with a series-connected filter of 1 mm Al + 0,5 mm Cu. The irradiated parts were at a distance of 20-30 cm from the tube and the dose was 85-114 Roentgen per minute. Both on the occasion of the irradiation of the cerebral hemispheres and also of the cerebellum all phases of cariokinesis of the limboblasts are noticeably in the peripheric blood, viz.: a distinct con-fusion of dependent reflectory activity, the fact that the clinical degenera-tion of nervous activity are strongest after 3-5 days, and considerable modi-fication of the metabolism of the nerve tissue itself. At the same time, the oxidation mechanism of the glycosis is interrupted. On the occasion of the irradiation of the cerebellum the composition of red blood changes, nucleus partitions become noticeable in the mother cells, and even binuclear erythro-cytes occur. On the occasion of the irradiation of the cerebrum such changes have as yet not been noticed.  
 The changes in peripheral blood on the occasion of the irradiation of the cerebral hemispheres and of the cerebellum are in a certain degree similar

TITLE: Changes in the central nervous system after exposure  
to ionizing radiation

PERIODICAL: Trudy Tashkentskoy konferentsii po mirnomu ispol'zova-  
niyu atomnoy energii, v. 3, Tashkent, Izd-vo AN Uzb.  
SSR, 1961, 53 - 58

TEXT: In continuation of earlier work the authors studied in greater detail changes in the nucleic acid content and histological changes in the cerebellum of guinea pigs after localized exposure to X rays. The DNA and RNA contents of the of the cerebellum (mean values in mg % for wet tissue) was estimated in 108 guinea pigs immediately after the exposure (i.e. before the appearance of cerebellar disorders); after 3-4 hours (initial phasis of changes); after 24 hrs. (peak of changes), as well as after 10, 15, 20 and 30 days; (period of gradual restoration). Immediately after the exposure the nucleic acid content appeared to be unchanged; after 3-4 hours a slight decrease. ✓

crease could be observed and after 24 hours the DNA content had decreased by 27.9 % and the RNA content by 26.4 % compared to the control levels. Owing to the cerebellar edema prevailing at that stage, however, the weight of the dried residue was 20 % lower in the experimental animals than in the control animals; hence the above values for wet tissue correspond to an actual decrease of only 7.9 % for DNA and of 6.4 % for RNA respectively. In the subsequent period (10-30 days) the nucleic acid level gradually returned to normal values. The cerebellum of 40 guinea pigs exposed to localized radiation in a dose of 9000 r and of 65 guinea pigs exposed to 16,000 r was investigated histologically. No gross changes were found immediately after exposure, but the microscope revealed some cell enlargement, beginning edema of the stroma and tigrolysis in some Purkinje cells of the ganglion cell layer. 3-6 hours after the exposure marked changes were found in all cortex layers; only a few cells retained their normal appearance. 24 hours after the radiation, changes culminated in the destruction of numerous cells: in some parts all Purkinje cells were destroyed, in others their number was diminished. In parts of the cerebellum more remote from the exposed area the changes were correspondingly less intensive. During the period of restoration
