Development of Upper Kasanian (Permian) sediments of Tartaria. L. M. Migonol'skiĭ. *Doklady Akad. Nauk SSSR* 61, 1075-8 (1948). The Buntsandstein (Lower) and Zechstein (Upper Permian) sediments in Tartaria are characteristically different in their contents of carbonate rocks and the composition of the waters circulating in them. Zechstein (av. from 29 analyses): 27.27% Ca, 7.80% Mg, 1.81% R₂O₃, 11.45% C. Buntsandstein (taken from 78 analyses): 4.30% Ca, 1.35% Mg, 0.24% Mn, 15.16% R₂O₃, 27.42% SiO₂. Average content in mg per l for saline Zechstein (av. of 76 analyses): 241.78 Ca, 52.40 Mg, 52.81 Cl, 115.32 S, 85.03 C, 8.25 Na + K. Buntsandstein (av. from 14 analyses): 77.26 Ca, 24.90 Mg, 6.90 Cl, 10.65 S, 66.94 C. Without counting the enrichment in Ca and Mg the presence of the other elements is not too far from the geochem. standard in Clarke's calc. of av. rock comp. Zechstein is prevalently an oceanic, Buntsandstein a continental series of sedimentary rocks. Thus the distinct differences in the Kasanian originated from repeated sea transgressions alternating with sedimentation of transported elastic material. In Tartaria the beginning of the Permian era showed most variable paleogeographic conditions by rhythmic shallowing of the sea, observed in the dolomite rocks, gypsum deposits with NaCl inclusions, celestite and relict anhydrite, and pseudomorphs after NaCl. These cannot be explained by fresh water or lagoon true depositions. W. T. 1948.

Aragonite from Dolinova, Tatariya — I. M. Muzapal'ski and N. M. Koryunov. *Tr. Akad. Nauk SSSR Ser. Khim. Nauk*, 1964, No. 1, p. 1083-1085, 1 fig., 2 tables. (English translation in *Journal of Earth System Science*, 1964, v. 49, p. 107-109.) In dolomite limestones of the Comancheg and Oxford horizons of Tatariya, the occurrence of aragonite on entirely or partly filled cavities and cracks is remarkable. The stratigraphic character of the dolomites is given in detail, with grain size distribution and mineralogical constitution of the heavy and light fractions, and a chem. analysis is given. Fe content relatively low. The morphological development of the aragonite is especially discussed from the conditions of crystal growth in narrow spaces, either as a fine-fibrous aggregate, or as free developed needles, or spherulites. $D = 2.01 \times 10^{-6}$ cm, $\alpha = 1.084$, $\beta = 1.083$, $\gamma = 1.512$; the chem. analyses are remarkable because of the variable SrO content of the crystals, 0.06% in the filled aragonite spherulites, 0.07% in crystals grown on the walls, 0.11% in spherulites. Spectrographic analysis shows the presence of Ba, Mn, Fe, Ti, and accessory Mg, Al, Si. The mineral is a typical crystal from circulating vadose waters coming from the surface, leaching out the dolomite. The low pH for the formation of aragonite is caused by the weathering of a slight overite content of the dolomite. (W. B. F.)

f

Barite from Middle Jurassic sediments of Tartariya
 L. M. Mikropol'skii and N. M. Kovyazin. *Zapiski Vsesoyuznogo
 Mineral. Obshchestva* (Mém. Soc. russe minéral.) **80**, 48-54
 (1951). The systematic study of the crystallographic habit
 observed in Jurassic barite deposits shows that $BaSO_4$ was
 formed in septariae with ophioclastic concretions, associated
 with calcite, pyrite, gypsum, and hydrogorthite of secondary
 origin, formed during the period between the consolidation
 of the rock, and the katagenetic and hypogenetic reactions.
 Barite, pptd from circulating subterraneous saline, was
 formed in close relation to the decomposition of FeS_2 in the

septariae, i.e. by a reaction of H_2SO_4 with $BaHCO_3$ in
 the saline solution. W. Fintel

Sphalerite in Devonian sediments of southwestern Tatarsiya L. M. Miropol'skii and G. L. Miropol'skaya *Doklady Akad. Nauk SSSR* 80, 425-8 (1951), et al. 40, 340-4. The association of sphalerite with pyrite and siderite is typical for wide regions of the eastern Russian platform. It is generally explained by diagenetic crystals from fine-disperse systems in a reducing medium. New deep-borings gave important results concerning the secondary character of the formation of ZnS from H₂O solutions, the mineral is often observed on the walls of cavities of the country rock. The metasomatism is regional. Not only is it associated with sphaeroiderite, but it is observed in all kinds of calcareous sediments and clayey sediments. The strongly reducing conditions are shown by the abundant organic fossils and bituminous layers locally rich in FeS, rarer with chalcopyrite. Quartz is usually older than ZnS, but calcite is always younger. Distinct crystals of ZnS are rare, mostly the mineral is fine-cryst. The crystals sometimes show a characteristic zoning with brownish and yellowish bands. The spectral analysis shows the presence of Fe (abundant), Cd, Cu, little Sn, and only traces of Mn and In. Local enrichments in Cd are not yet explained, also not the association with chalcopyrite. W. Eitel

U S S R .

Chalcopyrite in Devonian sediments of southeastern Tatars. L. M. Miropol'skiy and V. A. Polyakov. *Doklady Akad. Nauk S.S.S.R.* 81, 457-9 (1951).--Drill cores in Devonian limestones and aleuritic clays and aleurites of the Domaniya, Pashlik series, and of the Upper Giretan ages often show bituminous horizons rich in org. material. Pyrite, sphalerite, and chalcopyrite rich in org. material with quartz in cracks and fissures occur in these, associated with sulfides. Chalcopyrite is formed in concretions of the under-reducing conditions. Granular intergrowths of chalcopyrite with sphalerite are also observed in aleurites, e.g. in Krym-Saral and Mimbeyo. The identification of the sulfide minerals was made by ore-microscopic methods and specific etch reactions. The hydrothermal character of the Cu-Zn mineralization is confirmed by the widespread occurrence of the ores in the Devonian horizons in spite of their highly variable chem. compn., often with distinct indications of metasomatic reactions. The sphalerite always contains Cd as characteristic accessory element. The economic importance of the sulfide ores, however, is practically negligible. W. Eitel

TITLE: More on the Sulfide Mineralization in the Devonian
Rocks of Tataria (Yeshche o sul'fidnoy mineralizatsii
v devonskikh otlozheniyakh Tatarii)

PERIODICAL: Uch. zap. Kazansk. un-ta, 1956, Vol 115, Nr 16,
pp 251-266.

ABSTRACT: The author sharply criticizes the statements of B. A. Uspenskiy and N. V. Kirsanov (Uch. zap. Kazansk. un-ta, 1954, 114, Nr 7) in reference to his previous paper (RZhGeo, 1955, 3094) and reaffirms his point of view on the hydrothermal origin of the sulfide mineralization in the Devonian deposits of Tataria and the adjoining regions of Bashkiria and the Udmurt Republic. He denies the correctness of the view of N. V. Kirsanov on the sedimentary origin of this mineralization.

TITLE: Ankerite in the Lower Nivetican Deposits of Eastern Tatariya (Ob ankerite v nizhnezhivetskikh otlozheniyakh na vostoke Tatarii)

PERIODICAL: Uzh. zap. Kazansk. un-ta, 1960, Vol 116, Nr 3, pp 190-193.

ABSTRACT: The authors describe a concretion of ankerite from the base of a sandstone (D₁). The vertical diameter of the concretion is at least 10 cm. Megascopically the ankerite is dark gray and dense. Under the microscope, the principal part of the mass, localized in the central part of the concretion, is seen to have a granular structure. Isolated sections of fine-grained material may be seen against this background. In such sections the ankerite is uniformly turbid because of the dissemi-

Card 1/3

Ankerite in the Lower Silurian Deposits of Eastern Tadoussac (1957-58-5242)

nation of fine pelitic material. Coarser grained aggregates of ankerite are the result of recrystallization of the fine-grained material. Cone-in-cone structure in the upper and lower part of the concretion adds inhomogeneity to the ankerite. In those parts of the section, approximately at right angles to the direction of cone development, the ankerite has a megascopic mottled color. The cones in such sections have a concentric, zonal structure. The diameters of the bases of the cones do not exceed 0.5 cm, and the lengths range up to 1.2 cm. The microscope shows the individual cone to consist of a number of smaller cones enclosed within it. The number of these cones ranges from 3 to 14, and they are separated from one another by coatings of clay. The authors are inclined to believe that this cone-like structure developed in the ankerite by recrystallization of a special type, occurring at the surface of the concretion by metasomatism. The refractive indices of ankerite from the sections with the coarsest structure and of acicular crystals in the cones are No 1.742-1.738 and No 1.522-1.532. The specific gravity of the coarse-grained ankerite is near that of the acicular crystals. The ankerite in the cones, relative to the coarse-grained type, has
Card 2/3

SUBJECT: USSR/National Economy 25-5-10/35
AUTHOR: Miropol'skiy, L.M., Professor, Deputy Chairman of the Pre-
sidium of the Kazan Branch of the USSR Academy of Sciences
TITLE: For the National Economy (Dlya narodnogo khozyaystva)
PERIODICAL: Nauka i Zhizn' - May 1957, No 5, p 24 (USSR)
ABSTRACT: The most important section of the USSR Academy of Science in
Kazan is the chemical school headed by Academician A.E. Arbuzov.
Since its foundation in 1945, chemists have produced many new
phosphoro-organic compounds, which proved very useful for agri-
cultural purposes. "Oktametil", for instance, is an in-
secticide approved by the Ministry of Chemical Industry as
being a very effective vermin killer, especially suited to
destroy insects on cotton and citrus plants. A drug for curing
serious eye diseases (glaucoma) was developed by Academician
Arbuzov. It is a phosphoro-organic medicine approved for pro-
duction by the USSR Ministry of Health, as it has proved to be
superior to many imported drugs for similar purposes. The an-
organic chemistry laboratory developed a new highly effective
method for electric polishing of metals. Another useful con-
tribution of a Kazan scientist, E.A. Robinson, is the monograph

Mechanism of interorgan protein exchange S. V. Miropol'skiy (State Univ. Leningrad) *Izvestiya Leningradskogo Universiteta, Seriya Biologicheskie Nauki*, No. 5, 122-124 (1970). - Expts. with anguostomized dogs showed that intestine, liver, brain, muscle, and kidney sometimes retain protein metabolites (amino acids and polypeptides) from the blood, and sometimes release them to the passing blood stream. This interorgan exchange of metabolites is a very active replenishment mechanism serving the cells in each organ. Even the intestines have their intervals of withdrawing metabolites from the blood. Thus the metabolite content of the organs is sometimes lower, sometimes higher than that of the blood. There is a pos. correlation between the intensity of metabolite interchange and the concn. of protein metabolites in blood or tissues. Julian F. Smith

TITLE: Gravitational radiation of double stars

SOURCE: Astronomicheskii zhurnal, v. 42, no. 5, 1965, 977-980

TOPIC TAGS: gravitation field, double star, galaxy, galactic radiation, binary star
12,55

ABSTRACT: Two contradictory theories concerning the nature of the gravitational field responsible for gravitational waves are examined. The objects studied are stars of the W UMa type, whose density in the neighborhood of the sun is greater by a factor of 15 than the density of eclipsing variables of all other types; this relation holds true for most W UMa stars in the range of periods 0-1 day. The gravitational radiation of the part of the galaxy closest to us is determined almost completely by stars in this class. Using data on these stars and the formula for the

ACC NR: AP5025615

intensity of gravitational radiation of a system of two material points moving in circular orbits around a common center of inertia, the spectral density function of the galaxy is $\rho(T) = 2Nf(2T) \phi(T)$, where N is the number of W UMa stars in the galaxy, T is the period of the gravitational wave (see fig. 1). The total intensity of galactic gravitational radiation is $\approx 10^{38}$ ergs/sec. If all the galaxies of the universe had such a radiation intensity during the lifetime of the universe ($\approx 10^{10}$ years), the accumulation of gravitational radiation would be $\approx 5 \cdot 10^{-20}$ erg/cm³. In turn, the density of the flux of gravitational radiation near the earth would be $\approx 10^{-7}$ erg/sec·cm². In comparison with closely spaced double stars the

contribution of other sources of gravitational radiation is negligible. The value $5 \cdot 10^{-20}$ erg/cm³ therefore can be accepted (with an accuracy to one order of magnitude) as the lower limit of gravitational radiation in space. An appendix describes the method used to determine the number of W UMa stars in the galaxy. "The author expresses appreciation to Ya. P. Terletskiy, B. V. Kukarkin and P. G. Kulikovskiy for

Automation of Cold [Metal] Stamping Production

COVERAGE: The collection contains reports delivered at the Higher Scientific and Technical Conference by workers of machine and instrument plants, design organizations and scientific research and educational institutes. The Conference was sponsored by the Kuznetsk oblastskoye party committee. The participants observed a demonstration of the VZP plant with the Kuznetsk Administration of the 3 scientific and technical centers of the Machine-Building Industry) and by the Kuznetsk regional committee of the Communist Party (Kuznetsk Regional Administration of the 3 scientific and technical centers of the Machine-Building Industry). The purpose of the Conference was to discuss the achievements and practical experience (especially at the VZP plant) in the automation of stamping production. The Conference also served to acquaint a wide number of machine and instrument builders with the present state of automation in these plants and with the prospects for its further development. Reports dealing with experience in the design and operation of automatic devices, presses, and automatic production lines used to obtain preliminary work instructions. No personalities are mentioned. References accompany most of the articles.

2449 AERE-LA/Traas-400
ON THE INTERRELATION BETWEEN THE HYDRODYNAMICS OF STEAM-WATER MIXTURES, THE TEMPERATURE DISTRIBUTION IN A METAL AND THE DEPOSITION OF EASILY SOLUBLE SALTS IN HORIZONTAL STEAM-GENERATING PIPES. M. A. Syrtchevich, Z. L. Mirovskikh, and N. M. Anshin. Translated by J. B. Sykes from *ISSN: Atom. Nakh. S.S.S.R., Otdel. Tekh. Nauk* 432-44(1962). 10p.

Several series of experiments have been performed in a closed circulating system including heated vertical and horizontal portions of steam-generating pipes of various diameters. It was found that deposition of NaCl and Na_2CO_3 took place in the horizontal parts of boiler pipes when the temperatures of the upper part of the pipe wall were higher than those of the lower part. The probability of the occurrence of deposition increases with pressure. (M.P.G.)

TITLE: On the Operational Temperature Conditions of Horizontal and Inclined High pressure Steam generating Tubes (O temperaturem rezhime raboty gorizontalnykh i naklonnykh parogeneriruyemykh trub pri vysokikh davlennyakh)

PERIODICAL: V sb. "Gidrodinamika i teploobmen pri kipenii v kotlakh vysokogo davlenniya. Moscow: AN SSSR, 1955 pp 229-254

ABSTRACT: The article presents the results of experimental research on the operational temperature conditions of horizontal and inclined tubes with an internal diameter from 32 to 56 mm. The angle of inclination is from 0° to 10° , the pressure range is from 36 to 182 atm abs, and the heat transfer rate is from 40×10^3 to 230×10^3 kcal/m² hour. Description of the installation is given. Experimental methods are described in detail. Numerous graphs are presented. It has been established that there exists a considerable range of operational conditions during which increases are observed in the metal temperature of the upper parts of the tube wall. These increases are due

Card 1/2

SOV 124 58-3 3020

On the Operational Temperature Conditions of the High Pressure (cont.)

to unequal distribution of the vapor and the liquid phases over the height of the ~~cross~~ section. Such an overheating may cause damage due to cracking or corrosion. It has been found that the overheating Δt of a tube wall depends on the geometric dimensions of the tube, the reduced velocity of the liquid and the steam, the heat-transfer rate, and the pressure. The value Δt increases with an increase in the tube diameter and the heat-transfer rate, and decreases with an increase in the circulation velocity. With an increase in the reduced steam velocity, all other conditions being equal, Δt increases at first and begins to decrease later. With an increase in pressure there is an increase in the values of the limiting circulation velocity at which the values of Δt decrease to a small amount of the order of 5 to 10°. With an increase of the angle of slope to 10° at the pressure of 100 atm abs, the value of Δt decreases to about 13 or 14, and at higher pressures (140 to 180 atm abs) decreases approximately to 12. The article concludes that an employment of horizontal tubes in high pressure natural circulation boilers is not permissible. Bibliography: 4 references.

TITLE: Heat Emission to Water and Steam at Variable Heat Capacity Near the Critical Region (Teplootdacha k voblikskoy oblasti i teploemkosti (v okolo-kriticheskoj oblasti))

PERIODICAL: Zhurnal Tekhn. Fiz., 1971, Vol. 41, No. 10, pp. 1735-1741, USSR

ABSTRACT: The results of investigations of the local coefficients of heat emission to hot boiling water and to overheated steam at pressures of from 4 to 280 at are given. In this investigation where the water and the steam moved within a pipe in a turbulent flow, the distribution of the heat emission following was noticed in the regions of sub- and overcritical pressures: 1) The application of the general formula for the computation of the heat emission to hot boiling water or to overheated steam cannot give satisfying results in those temperature regions where the values of α and Pr change in connection with the variation of the specific heat of the medium. 2) A formula is given here for the computation of the local values of the coefficient of the heat emission to water and steam within the above mentioned limits of the parameter variation. This contains the known figures: Nu , Re , and Pr . The mean current temperature is assumed as the determining temperature for the computation of Nu and Re . In the computation of Pr the determining temperature is assumed to be equal to either the

TITLE: The generalisation of experimental data on temperature conditions in the metal of horizontal and slightly sloping boiling tubes (Obobshcheniye eksperimental'nykh dannyykh po temperaturnym rezhimam metalla gorizonta'nykh i slabo naklonennykh kipyatil'nykh trub)

PERIODICAL: Teploenergotika, 1958, vol 5, No.6. pp. 56-60 (USSR)

ABSTRACT: When a steam/water mixture moves in slightly sloping tubes, it separates out into layers, so that the tube is unevenly heated. The effect depends on a large number of factors and many tests had to be made in the study of it. The tests were made on two semi-full-scale rigs: a closed-circuit circulating system with an oil-fired furnace in Regional Electric Power Station No 2. of Mosenergo, and a rig of the direct-flow type using externally supplied steam and water in the Heat and Electric Power Station of the All-Union Thermotechnical Institute, where the experimental sections were radiantly heated by electric furnaces. In most tests the tubes were heated uniformly over the perimeter, but some were heated from one side only. In the tests at the All-Union Thermotechnical Institute, in addition to wall temperature measurements, the steam/water flow structure was studied by means of γ irradiation. The test conditions are tabulated; some of the results have already been published. The present article attempts to work out the test data

Card 1/3

307/96-58-6-11/24

The generalisation of experimental data on temperature conditions in the metal of horizontal and slightly sloping boiling tubes.

obtained in this work by means of dimensionless criteria, and a procedure is proposed for calculating the wall temperatures of horizontal and sloping boiling tubes. Separation into layers occurs over a wide range of circulation and pressure conditions. Under such conditions the temperature of the lower part of the tube, where the water is, is little above the saturation temperature; in the upper part of the tube cooling occurs by transmission of heat to the steam. An equation is given to determine the maximum temperature and the assumptions made in its derivation are described. To use this equation directly for practical calculations, one would need to know the variations in the heat-transfer coefficient to wet steam in contact with the upper part of the tube and the proportion of the tube perimeter that is free of liquid under various experimental conditions. As this information is lacking, the test data must be formulated as dimensionless criteria and the relationships between them indicated. The appropriate dimensionless formulae are then derived. Equation (2) for the temperature difference between top and bottom of the tube, is a function of 14 dimensional magnitudes, and is reduced to an equation with nine dimensionless criteria. Available test data is then used to express this formula concretely. Criteria required in the work are plotted in figs. 1. and 2. Finally, an expression is

Card 2/3

SOV/96-58-6-11/24

The generalisation of experimental data on temperature conditions in the metal of horizontal and slightly sloping boiling tubes.

obtained by means of which the test data can be worked out. A graph of the test results for a uniformly heated horizontal tube worked out in this way is given in fig.3, with an equation defining the best line through the points. The scatter of the test points is accentuated because they relate to a variety of rigs and not all are equally accurate. The concurrence between the straight line and the results of various authors is discussed. When the tube is heated from one side only, the highest temperatures occur on the side of the tube where the heat flux is greatest. The maximum temperatures were the determining factor in working out the test data and an equation is given that corresponds to the results given in fig 4. The case of sloping tubes is similarly treated by an equation and fig.5. The results show that the least permissible circulation rates depend on numerous factors, but at high temperatures and rates of heat flow, very high circulation speeds would be required to secure uniform temperature distribution round the tube. The possibility of drops of highly-concentrated salt solutions forming in the tubes must be considered, and the probable behaviour of various salts present in boiler water is discussed. There is 1 table, 6 figs & 12 lit references (Soviet)

TITLE: Radioactive Deposits in the Steam Section of Atomic Power Plants
(Radioaktivnyye otlozheniya v parovodyanom trakte atomnykh silovykh ustanovok)

PERIODICAL: Physics and Thermotechniques of Reactors (Fizika i teplotekhnika reaktorov), Supplement Nr 1 to Atomnaya Energiya, 1958 (USSR)

ABSTRACT: When dealing with the problem of radioactive contamination in steam circulation systems with direct steam generation, the quantity and the compositions of the radioactivities in the steam must be known. It is necessary also to know the type, the radiation energy, and the half-lives especially of γ -rays, because their presence renders access to the steam parts difficult. In heterogeneous boiling water reactors there are three causes for the radioactive contamination of steam-carrying parts:

- 1.) The cans of fuel elements have become leaky and radioactive fission products find their way into the steam circulation system.
- 2.) Corrosion- and erosion products, which have been within range of the active part of the reactor for a long time, now that

Card 1/2

Radioactive Deposits in the Steam Section of
Atomic Power Plants

65-11-16/18

they have become radioactive, penetrate into the steam section through the circulation system.
3.) Corrosion- and erosion products of the steam section penetrate into the active part of the reactor where they are activated, after which they again enter the steam duct after some time. The amount of radioactive contamination in the water-steam part was calculated and the radiation doses for those parts were determined in which radioactive deposits may occur. There are 1 figure, 2 tables, and 10 references, 6 of which are Slavic.

TITLE: Radioactive Deposits in the Steam-Water Circuit of Atomic Power Plants

PERIODICAL: V sb.: Fiz. i teplotekhn. reaktorov. M., Atomizdat, 1958,
pp 205-215

ABSTRACT: At atomic power plants with heterogeneous boiling reactors, three factors cause radioactive contamination of the steam-water circuit: (1) leaks through the jackets of heat-producing elements that result in nuclear fuel and fission products getting into the loop; (2) elution of corrosion products and erosion of materials that were in the core for a long time and that have considerable activity; (3) activation of erosion and corrosion products of the steam-water circuit which is outside the reactor core and activation of the outside substances that penetrate into the loop. Most difficulties in separating the

Card 1/2

SOV/112-59 4-6654

Radioactive Deposits in the Steam-Water Circuit of Atomic Power Plants

steam-water circuit of a boiling reactor are due to radioactive isotopes that have a radioactive half-life of a few dozen days. Formulae are developed for determining the radioactive contamination of the steam-water circuit and the irradiation dose coming from contaminated circuit components. The hazard of chemical-element activation and of loop contamination by fission products is discussed. Estimates made for large atomic power plants with boiling reactors have shown that 24 hours after the turbine shutdown, the irradiation doses due to radioactive deposits near the turbine do not exceed permissible values. In the case of a damaged jacket of a heat-producing element and penetration of a few hundred grams of the nuclear fuel into water, the irradiation doses can exceed the normal values several times.

TITLE: Critical Heat-Flow During Uniform and Non-Uniform
Heating of the Perimeter of Steam-Raising Tubes
(Kriticheskiye teplotnyye potoki pri ravnomernom i
neravnomernom nagraevanii perimetra i potokoviznashchivaniya
trub)

PERIODICAL: Tekhnicheskaya fizika, 1957, No. 11, pp. 54-69 (USSR)

ABSTRACT: A good deal of work has been done on critical values
of heat flow in vertical tubes with uniform heating.
But in practical conditions the tubes are often
non-uniformly heated, by the use of forced draft and
critical heat, thermal loading in boilers can be
raised to a great extent there is critical boiling and
tubes are damaged. This work describes tests made
with uniform and non-uniform distribution of heat flow
round the tube perimeter. For uniform heating the
tubes in the experimental section were made of steel
EY1-1T; the length of the heated section was 150 mm
and the internal diameter 5.0 - 6 mm. In the tests
with non-uniform heating, tubes of variable wall

Card 1/4

SOV/9-11-11-21/21

Critical

test-f... of the perimeter of the... tubes
 thickness as depicted in fig. 2, were heated by
 electric current. The requisite range of wall
 thickness was obtained by turning the steel tubes
 off-the-trade in lathe. The eccentricity was 0.05,
 so that the tubes were heated the test-flow
 diameter was as sketched in fig. 2. Because of the
 100-mil. length of the perimeter of the
 experimental tube, the temperature is also
 uniform and there is best transfer of thermal
 conductivity in the metal. To reduce this effect,
 the low-temperature shells were milled in the outer
 surface of the tubes as shown in FIG. 1. The test
 equipment is illustrated in fig. 3a and b. The tests
 are made with superheated steam at pressures up to
 300 lb and temperatures up to 400°C. The experimental
 procedure and instrumentation are described. The
 crisis condition, that is transition from nucleate
 boiling to filmwise boiling, may be defined as:

Card 2/4

SOV/91-5 -11-11/21

Critical Heat-Flow During Uniform and Non-Uniform Heating of the Perimeter of Steam-Rising Tubes

recognise at high pressures and the methods used for this observation are described. The test results obtained with uniform tube heating are graphed in Fig.4. The results are in good agreement with previously published data, including some American results. The corresponding test results with non-uniform heating of the tube are plotted in Fig.5. The critical heat flow is of the same general character as with uniform heating but the numerical values are higher. In Fig.6, a graphical comparison is made between test data obtained with uniform and non-uniform heating. It will be seen that the critical thermal flux on the front surface of the tube with non-uniform heating is 1.6 - 1.8 times

Card 3/4

SSV/94-97-11-10/21

Critical out-flow from uniformity of the perimeter of steam-raised tubes higher than in uniform heating. This may be explained by the presence of rotary motion in the tubes. There are 5 figures and 4 Soviet references.

PURPOSES: This work is intended for scientists and engineers working in the field of steam boilers.

CONTENTS: This is a collection of 9 articles on the circulation of water and water-vapor mixture in boilers, bubbling processes, pulsation of pressure, temperature fields in combustion chambers, radiation heat transfer between gray bodies, and the solution of nonlinear problems of mathematical physics. There is also an article describing processes occurring in the steam boiler of a solar heat energy station. References appear at the end of each article.

were conducted at the hydroelectric laboratories in cooperation with Heat and Electric Power Plant (TEP) No. 9.

Barabov, G. O.; Ya. G. Vinokur, V. A. Kolovalov, and V. I. Fatukhov. Experimental Investigation of Vapor and Gas Contents in a Bubbling Process 40

It was found that the distribution of volume vapor content and air content along the column of two-bubbling volume at insignificant reduced velocities of two-bubbling volume is the same as the distribution of volume vapor content at low boiler water salt content; remains qualitatively the same under various pressures and characteristics of the perforated plate. An increase in the weight level at atmospheric pressure results in a decrease of vapor content. An increase in the reduced velocity of steam when the water is of low salt content increases the volume vapor content.

Shaykov, B. I. Pulsations of Pressure in the Flow of Gas-Liquid Mixtures in Pipes 46

The article describes experiments in pressure pulsation in

Four 14 long pipes of different diameters—25.8, 47.5, 76.7 and 99.6 mm. The flow velocity changed from 0.2 to 5m/sec. The gas content changed from 0.05 to 0.95. Graphical representation of experimental results are given.

Maruyama, T. L., and B. I. Shmezerova. Investigation of a Flow of Vapor-Water Mixture in Pipes by Radiation 53

In this article the authors describe problems in determining the average values of steam volume contents ϕ in pipes and in conduits of rectangular cross section. The results obtained are also valid for conduits of arbitrary geometrical shapes. Diagrams and graphs are given.

Khristalev, B. A; and S. S. Pilsimonov. Temperature Fields in Combustion Chambers 62

Three kinds of furnace heating chambers were investigated. Experimental data on the temperature distribution of approximate self-modeling temperature fields are given. The results are according to load. It is stated that the approximate independence of dimensionless temperature fields from the radii occurs in various combustion chambers which differ from each other according to geometric characteristics and the type of combustion processes.

Shogolev, D. A. Steam Boiler of a Solar Heat Energy Station 70

The author presents data on the performance of steam boiler operating on solar heat energy. General diagrams of a boiler and tables of principal characteristic are given.

Surinov, Yu. A. Investigation of Radiation Heat Transfer in Systems of Gray Bodies 79

The author develops a theory of radiation and radiation heat transfer. The equations appearing in this article permit a theoretical-probability interpretation. The article is divided into two parts: 1) Solution of a stated problem on radiation heat exchange in a system of gray bodies in a diathermic medium, and 2) Solution of a stated problem of radiation heat

NOTES: This collection of articles is intended as a tribute to the memory
 of Academician G.M. Ershinoborov.

CONTENTS: The collection contains sixty articles by former students and
 associates of the deceased Academician. The articles deal with problems
 of a wide range of subjects in the field of power engineering: problems
 of the regional development of electrical and thermal power engineering,
 power engineering technology and the physics of combustion. In personalities
 are mentioned. References are given after most articles.

AUTHOR: Miropol'skiy, G.L., Candidate of Technical Sciences
TITLE: Temperature Conditions in the Metal of the Steam-heating Surfaces of Once-Through Boilers (Temperaturnyy rezhim metalla parogeneriruyushchikh poverkhnostey pryamotocnykh kotlov)

PERIODICAL: Teploenergetika, 1959, Nr 3, pp 40-44 (USSR)

ABSTRACT: This article is a general review of published work on the subject. As steam conditions are raised, the operating temperatures in metal heating-surfaces approach limiting values. It is, therefore, important to develop methods of calculating the metal temperature throughout the steam/water path of the boiler. Temperature conditions when operating below the critical pressure are first considered. Diagrams of the temperature distribution the flow and the temperature of the internal wall surface of a tube are given in Fig 1. The diagram relates to the whole length of a coil of a once-through boiler with uniform heat flux distribution round the surface and length of the tube. In the first section of the tube the temperature of the working medium and of the wall are below the saturation temperature; here, existing

methods of calculating the temperature are well established. However, false results are likely to be obtained in temperature and pressure regions where the specific heat of the medium is rapidly changing. Several previously published methods of making these calculations are reviewed. The effect of the change-over from dropwise to filmwise evaporation is considered. Typical data on temperature changes in the walls of the tube with increase in the heat flux at high pressures are plotted in Fig. 1. It is shown that for low values of steam content in the working medium the maximum permissible thermal fluxes are governed by the conditions of transfer from bubble to filmwise boiling. Graphical data about the limiting conditions at which the transfer to filmwise boiling occurs are seen in Fig. 3. Values of the critical and permissible heat fluxes at pressures of 26, 100, 180 and 220 atm obtained in tests with tubes 8 mm diameter heated over a length of 160 mm are plotted in Fig. 4. Some ideas about the safe operation of boiler tubes during filmwise

of Once-Through Boilers

boiling are given by superposed curves of permissible thermal fluxes. The possible occurrence of dangerous conditions at the start or the end of the evaporative zone is explained. Conditions are somewhat more difficult if the steam-raising tubes are arranged horizontally or with a slight slope, as in Fig.1b. Uniformly-heated horizontal tubes are treated in equation (4) and equation (5) refers to a tube heated from one side only. Temperature conditions at super-critical pressures are then considered. Here a single-phase medium flows through the entire boiler but the use of ordinary methods of calculation of heat-transfer coefficient with forced convection can lead to serious errors in a number of cases. The temperature changes of the medium and the walls for this case are plotted in Fig.5, which refers

AUTHORS: Miropol'skiy, Z. L., Shits in, M. re.
 TITLE: Critical heat flows for water boiling in channels
 PERIODICAL: Atomnaya energiya, v. 11, no. 6, 1961, 515 - 521

TEXT: Experimental data obtained by several authors are evaluated and analyzed by introducing dimensionless critical parameters. Such parameters may be interrelated by $\frac{q_{cr} l_0}{a' r_0} = f\left(\frac{w_0 l_0}{\nu'}, \frac{w_0 l_0}{a'}, \frac{r}{c_p T_s}, \frac{a''}{a'}, \frac{\rho'}{\rho''}\right)$ (1).
 γ - specific weight, (kg/m³), ν - kinematic viscosity (m²/sec), μ - dynamic viscosity (kg·sec/m²), σ - surface stress, r - evaporation heat, λ - heat conduction coefficient, a - thermal diffusivity, T_s - saturation temperature, w_0' , w_0'' - reduced velocities (m/sec), q - specific thermal flux, q_{cr} - specific critical heat flux, l_0 - characteristic length (m).
 Analysis of available data shows that channel cross-sectional dimensions
