Wolframite near Kounrad. N. I. Nakovnik. *Rakus Metal.* 1, 1-5 (1935); *Neues Jahrb. Mineral. Geol., Ref. II*, 1937, 210. --The deposits are at the Göllich Brunnen, 7 km. from the Cu deposits of Kounrad. They consist of quartz veins in granite or quartz-porphyrus in the neighborhood of which the granite has been converted to gneiss and contains topaz, fluorite, pyrite, wolframite and a little chalcopyrite. The most important deposit of wolframite is at the Quartzberg, where it is in crystals usually 2-3 sometimes 10 cm., long. Analysis: WO, 75.81, Mn 10.34 and Fe 0.7.83%. C. A. Silberrad

Secondary quartzites and their relation to other metamorphosed rocks. N. I. Nalovnik. *Soviet Geol.* 8, No. 11, 12 (1948); 71: 32, 3310. In the Alta, zonyite, angelite, ilmenite ($FeTiO_3$, Fe_2O_3) and lazulite were found as components of secondary quartzites. Two tables give the order of formation of various secondary quartzite minerals under various metamorphosing conditions: rutile, ilmenite, hematite, quartz, andalusite, topaz, muscovite, tourmaline, dumortierite, lazulite, angelite, pyrite, corundum, chaspol, cerussite, chlorite, kaolinite, alunite, barite, in the pneumatolytic and hydrothermal phases and jarosite, limonite and kaolinite following in the surface layer. Secondary quartzites, their mineral facies, genesis, and practical importance. N. I. NAKHVINIK. *Bull. acad. sci. U.R.S.S., Ser. geol.* 1947, 133-50; abstracted in *Chem. Zentr.*, 1947, II [5/6] 200.—Secondary quartzites are defined as metasomatic formations, i.e., changed effusive rocks containing, besides quartz, pyrite, hematite, sericite, alunite, kaolinite, andalusite, diaspore, corundum, pyrophyllite, sunyite, dumortierite, and topaz. Secondary quartzites are found mostly in East Kazakhstan and also in the Caucasus, Ural, and Altai mountains. M HA.

Alunite, types and relations to country rocks and ore veins. N. I. Nakovnik. *Zapiski Vsesoyuz. Mineral. Obshchestva* (Mem. soc. russe mineral.) 77, 55-64 (1948).— The crystallochem. formula is $KAl_3(SO_4)_3(OH)_4$, with a partial substitution of Na for K. Doelter distinguishes the volcanic genesis of alunite, and a hydrothermal type in veins, and a third type characterized by exogenic reactions of H_2SO_4 (from oxidized FeS, and S) with country rock. In general, alunite is post-volcanic, formed under low-temp. conditions with pseudomorphs after feldspar. Alunite is a typical mineral of the epithermal metasomatic formation in secondary quartzites, replacing especially the higher siliceous aluminosilicates, but not minerals with Ca, Fe, Mg (limestones, serpentinites, marls, etc.). Liparites, porphyrites, trachytes, and their tuffs and breccias are principally affected by alunite; basalts and diabasites only rarely changed to alunite, ultrabasic rocks never. The discussion of more than 200 analyses shows that the higher the basicity of the original rocks, the higher is the Na_2O content of the resulting alunite. Andesites have a $K_2O:Na_2O$ ratio of 0.2 to 2:1; the corresponding ratio for porphyrites is 0.4 to 2.7:1, and for dacites 0.7 to 4:1 (av. 2.2:1). Nearly pure K alunites are derived from K-rich porphyrites, trachytes, and rhyolites (ratio 8:1).

The analyses of alunite-bearing rocks show the predominance of K alunites derived from high-silica rocks. In cavities in dacites, the ratio $K_2O:Na_2O$ may even be 12:1, or 20:1, but Na alunite is never observed in veins in siliceous rocks. There is a distinct difference between the metasomatic alunites discussed above and hydrothermal deposits of alunite on the walls of cavities, formed by H_2SO_4 -contg. waters in the country rocks which often transfer the alkali ions from a distance. The optical consts. of K alunite are characteristically different from those of Na alunite, and a table is given which shows the correlation of the $K_2O:Na_2O$ with n_s for 20 samples. Na alunites have a birefringence of 0.005 to 0.012, K alunites of 0.018 to 0.020. The silicification of the country rock to quartz, chalcedony, or opal during alunite formation is highly significant. The paragenesis of SiO_2 minerals with alunite is assocd. with pyrite, or hematite and rutile, and in minor amts. by diaspore, dickite, zunyite, and S. Zeolites, carbonates, sericite, chlorite, epidote, and similar minerals are absent. Alunite rocks are often accompanied by veins with minerals of Au, Ag, Hg, Sb, Pb, Zn, Cu, Fe, Sn, Mo, Bi. Kaolinization and propylitization with alunite is observed in ore deposits all over the world. In cryst. schists alunite is entirely absent, also in granites, gneiss, skarns, and contact hornfelses.

CO

Metamorphic crystallization with constant volumes
N. I. Nakovnik. *Zapiski Vostochn. Mineral. Obshchestva*
(Mem. Soc. Russ. mineral.) 78, 270-2 (1949).--The mechanism of metamorphic reactions is chiefly characterized by the impregnation of preexisting mineral complexes by a "posthumous" soln. chiefly of magmatic origin, or as juvenile waters, soln. ascending along channels and throughout the capillary system of the solid framework of the rock. The typical formation of pseudomorphs by chem. reactions, "molecule for molecule," replacing the "host" minerals is observed in saussuritized feldspars, or in the alunitization and kaolinization of andalusite, with quartz and diaspore, the change of biotite to a mixed aggregate of zirconite, rutile, and pyrite. Lindgren's law of "constant volumes" for the host and the reaction products is an important principle in petrography and ore deposit studies. Particularly interesting examples are given, among which the following are taken from the hydrothermally changed lavas of Kazakhstan: *dickite*, replacing biotite and plagioclase, filling the cavities of the lava. In the first case, rutile is simultaneously formed with the dickite, in the second example free SiO_2 crystal, as quartz. Particularly instructive are the parallel orientations of the dickite parcels in the layer structure of the original mica. Less pronounced are the orientation effects of dickite in pseudomorphs after plagioclase. The pseudomorphs of *alanite* after feldspar (with some quartz) are characteristic because of the absence of every influence of the replaced structure on the growth of the new product, although the original volume is entirely preserved and filled. Alunitized micas always show the orientation of the crystals parallel to the cleavage plane, like in the dickite pseudomorphs.

НАКОВИК, Н.И.

1. Mineral facies, genesis, and practical importance of propylitized rocks. N. I. Nakovnik. *Zapiski Vsesoyuz. Mineralog. Obshchestva (Mém. Soc. russes minéral.)* 83, 85-91 (1954).—N. defines the propylites as a complex of uraltized, epidotized, chloritized, or albitized rocks, distinguished from sericitized rocks, secondary quartzites and greenstones of regional-metamorphic origin. Propylites are hydrothermal decomn. products of primary intermediate or basic effusive rocks, with albite, adularia, uranite, or actinolite, epidote, chlorite, rutile, carbonates, quartz, sericite, and pyrite. They are intimately connected with hydrothermal ore deposits of Au, Ag, Cu, Zn, Pb, As, Sb, Hg, W, Mo, and subordinate Sn, Ni, Co, Pt, assocd. with veins of ankerite, calcite, rhodochrosite, quartz, etc. The chem. and mineralogical compn. of propylites derived from andesitic-dacitic or dioritic rocks near the ore veins changes in a characteristic zonality: in the inner zones, next to the ores the quartz-sericite assocn. prevails, while epidote, chlorite, and actinolite are typical minerals of exterior zones. Propylites derived from basic rocks (e.g. gabbros) show the type of listvenites, high in carbonates and sericite, often with Cr-mica. The inner zones are always smaller than the exterior zones. This is very characteristic for the reactions (amphibole, albite, epidote) → (chlorite + pyrite) → KCO₃ → (sericite, quartz, sulfides), with a gradual change of pH from 11 to 8

in the first group, to 9 to 7 for chlorite + pyrite, to 8 for KCO₃, to 7 to 6 in the last group. The first minerals changed by propylitization are the melanocratic silicates, followed by plagioclase, and last the K feldspar. From a review of propylites from important ore deposits, N. gives two diagrams which demonstrate the chem. changes occurring in intermediate, and in basic rocks during propylitization, especially for SiO₂, Al₂O₃, FeO, Fe₂O₃, CaO, MgO, Na₂O, K₂O, CO₂, FeS₂, Cu, and Au. In the direction from the exterior to the inner zones the data for SiO₂ and Al₂O₃ are not essentially variable, but CaO, MgO, FeO, and Fe₂O₃ decreased continuously, more intensely in the andesitic-dacitic rocks than in those of gabbroidal type. Na₂O and K₂O behave reciprocally, with a max. in Na₂O, a min. in K₂O, for the epidote-chlorite zones. Parallel to the enrichment in K₂O in the inner zones, H₂O, CO₂, and sulfides are increased, and Cu and Au are parallel to the enrichment in the volatiles. Si, Al, Ti are the least mobile elements, more mobile are Ca, Mg, Fe, Mn, most mobile Na, K, Cu, Au, and the volatiles coming from deep-seated sources. A rough parallelism exists with the ionic radii of these elements. The rare and exceptional hydrothermal rock type of the beresites (quartz-muscovite aplites, without any K feldspar) in the Au ore veins of Bereznovsk (Ural) is in some respects analogous to the inner zone formations of propylitized rocks.

Investigation of Products Obtained

PERIODICAL: Plasticheskiye massy, 1960, No. 10, pp. 60-61

TEXT: Proceeding from acrylonitrile the authors synthesized the following compounds: di-($\beta\beta'$ -cyanethyl)-sulfide; di- $\beta\beta'$ -cyanethyl ether; furthermore, $\beta\beta'$ -cyanethyl ethers of ethylene-, diethylene- and triethylene glycols and butanediols. By alcoholysis by means of 2-ethyl hexanediol one obtains the 2-ethyl hexyl esters of oxadipropionic acid, 2,4-dioxahexane dicarboxylic acid-1,6, 2,6-dioxaoctane dicarboxylic acid-1,8, 2,4,6-trioxaoctane dicarboxylic acid-1,8, 2,4,6,8-tetraoxadecane dicarboxylic acid-1,10, and thiodipropionic acid. [Abstracter's Note: the conditions under which the alcoholysis was performed are not indicated]. These esters were found to be resistant to frost down to -45 - -58°C (determination by L. I. Burinova), and yielded, when mixed

TITLE: A Voice of Instigators (Golos podstrekateley)

PERIODICAL: Radio, 1957, Nr 2, pp 59-60 (USSR)

ABSTRACT: A review of activities of "Radio Free Europe" is presented.

A group of American magnates founded the "Crusade for Freedom" organization in 1949, which quickly built a network of radio stations in Western Europe. "Radio Free Europe" operates 29 radio stations, that transmit 20 hours a day to Poland, Czechoslovakia, and Hungary, and 8 to 10 hours a day to Rumania and Bulgaria. Its headquarters are in Munich, and the total personnel number 1,200, of whom 120 are American citizens. S. Mikhal'skiy, a Pole, and former employee of the Munich radio center, related in the Polish press that Hans Fisher, Chief of the Security Division of "Radio Free Europe", made it clear that obtaining a permanent job there depends on good relations with the Security Division and with the American Intelligence. The West German magazine "Spiegel" commented that "Radio Free Europe" can speak with the voice of a private organization, and still be taken as the official voice of the USA. The role of "Radio Free Europe" in the Hungarian uprising of 1956 is discussed in the article, and a number of West European publications are quoted in this connection.

TITLE: Results of experiments on deoxidation of titanium

SOURCE: Tsvetnyye metally, no. 9, 1966, 78-80

TOPIC TAGS: titanium alloy, titanium zirconium alloy, titanium gadolinium alloy, titanium yttrium alloy, titanium deoxidation, metal property, OXYGEN, ZIRCONIUM (CONTAINING ALLOY, ALLOY COMPOSITION)

ABSTRACT: The possibility of lowering the oxygen content in vacuum arc-melted titanium by alloying with zirconium, gadolinium or yttrium has been investigated. Commercial-grade titanium with addition of the above alloying elements was double melted in a vacuum of 0.012—0.1 mm Hg into 5 kg ingots 130 mm in diameter. It was found that zirconium lowers considerably the oxygen content. For instance, while unalloyed commercial-grade titanium contained 0.102% oxygen, an alloy with 1.5—2.5% Zr contained only 0.055—0.075% oxygen. Results of experiments with yttrium and gadolinium were inconclusive due to the

AUTHORS: Busev, A. I.; Naku, A.; Rudzit, G. P.

TITLE: Use of l-mercaptopropionic acid derivatives in analytical chemistry. Communication 3: l-mercaptopropionic acid and some of its anilides as reagents for extraction-photometric determination of molybdenum

SOURCE: Zhurnal analiticheskoy khimii, v. 19, no. 3, 1964, 337-345

TOPIC TAGS: molybdenum, determination, extraction, photometric extraction determination, mercaptopropionic acid, mercaptopropionic acid derivative, phenetidide, anisidide, touidide, analytical chemistry, quantitative analysis

ABSTRACT: A study was made of the interaction of Mo(V) and Mo(VI) ions with l-mercaptopropionic acid (I) and some of its derivatives: o- and p-phenetidide, o- and p-anisidide, o- and p-toluidide-l-mercaptopropionic acid. It was established that I and its p-phenetidide interact with Mo(V) and Mo(VI) ions in the ratio of 2:1 (In fig. 1: the tangent of the angle of inclination numerically

Card 1/6

ACCESSION NR: AP4019509

equals the number of moles of reagent interacting with one mole of Mo). The compounds of molybdenum with p-phenetidine-1-mercaptopropionic acid (II) are most readily extracted with a 1:1 mixture of isoamyl alcohol and benzene, and the compounds with I are extracted with a 1:1 mixture of isoamyl alcohol and chloroform, when diphenylguanidinium or benzylthiuronium cations are present in the aqueous phase. During extraction one diphenylguanidinium or benzylthiuronium cation is added to a complex anion of Mo(V) with I and two cations are added to a complex Mo(VI) anion (fig. 2). Extraction-photometric methods were developed for the determination of molybdenum with I and with II in the presence of other elements. A sample containing molybdenum is treated with a solution of I and benzylthiuronium chloride, extracted with 1:1 isoamyl alcohol:chloroform solutions and the optical density is measured and compared with a calibrated graph. It was found that: Cr, Ti, Co, Ni, Zn, Al sulfate and nitrate ions do not interfere; in the presence of large amounts of vanadate and Fe (III) ascorbic acid should be added; Cu ions lower the accuracy of the determination; and very large amounts of W make determination difficult, but with smaller amounts, the optical

Card 2/6

ACCESSION NR: AP4019509

density may be measured at 350-365 and at 430 millimicrons. A similar determination may be made with II, using 1:1 isoamyl alcohol:benzene solution for extraction and measuring the optical density at 360 millimicrons. It was found that: Cr (III), Ti, Co, Ni, Zn, Al, Fe and V do not affect this determination; Cu lowers the accuracy; and W in a 100:1 ratio to Mo has no effect. I does present an odor problem; II has no odor. Orig. art. has: 2 tables, 5 figures and 6 formulas.

TITLE: The Centralized Supply of Hydrogen to Generators (Tsentral-
izovannoye snabzheniye vodorodom generatorov)

PERIODICAL: Energetik, 1958, Nr 11, pp 21-22 (USSR)

ABSTRACT: In order to improve the exploitation of the hydrogen cool-
ing of electric machines, Engineers G.D. Vul'man and V.S.
Ivanov, of the Mosenergo TETs, have realised a new system
for the centralized supply of hydrogen to the generators
of power-stations. This consisted of installing a recept-
acle with a capacity of 10 cuM of hydrogen at a pressure
of 10 atm. near the machine room. Next to the receptable,
a building with a gas ramp for discharging the hydrogen
balloons into the receptacle was erected. Gas pipes con-
nected the receptacle with each generator. A detailed

Title : On a change of a boundary condition of the flat problem in the theory of elasticity

Periodical : Dok. AN SSSR 98/1, 27-29, Sep 1, 1954

Abstract : The so-called flat (two-dimensional) problem of the theory of elasticity, solution of which usually has been reduced to finding two functions satisfying the boundary condition of Muskhelishvili, can be solved by a slight change in the boundary condition, namely, by expressing the variable unknowns in parametric forms of periodic functions. TITLE: Caterpillar drive for heavy machines. Class 84, No. 178753

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 3, 1966, 155

TOPIC TAGS: tracked vehicle, vehicle component

ABSTRACT: This Author Certificate presents a caterpillar drive for heavy machines, particularly excavators, including a lower frame and caterpillar carriages. To improve maneuverability and to decrease power requirements during turning, the lower frame is equipped with a pivot plate which can rotate in the horizontal direction and which is connected with the carriages so that it can operate vertically with the help of a lifting device (see Fig. 1). As an additional feature, the lifting devices (hydraulic cylinders) are rigidly connected to the lower frame and are pinned to the

1982. Leadless and tin-free opaque glazes for wall tiles and majolica.—
 A. A. NALBANDYAN (*Sov. Keram.*, 8, No. 1, 19, 1981). White and coloured opaque
 glazes are very suitable for tiles, etc. Normally lead glazes are used for this purpose
 with SnO_2 as an opacifier. Scarcity of Pb and Sn cpds. necessitates the use of
 substitutes, e.g. Sb, Ti, Ce, As, F and Zr cpds. In 1947 a Russian research institute
 developed the following opaque glazes for tiles, etc. made of Moscow and other
 clays (m.p. 950°–1,000° C.): *W-Zr white glazes*: In these PbO and Pb_2O_3 are substituted
 by cheap B cpds, e.g. colemanite ($\text{Ca}_2\text{B}_6\text{O}_{11} \cdot 8\text{H}_2\text{O}$) or hydroboracite
 ($\text{CaMgB}_6\text{O}_{11} \cdot 8\text{H}_2\text{O}$). An increase of alkali content beyond 0.3 mol. and of B_2O_3
 above 0.4 weakens the opacification and causes crazing. To obtain the necessary
 gloss and to lower the m.p. a small amount of TiO_2 , which has a high refractive index
 (2.5–2.9), is added to the glaze. Up to 2% TiO_2 in the frit lowers the m.p. of the
 glaze by 20° C. and increases the gloss by 3%; in addition, TiO_2 intensifies the
 opacification and imparts a pleasant warm tone to the glaze. As a substitute for
 Sn, de-ferrized Zr cpds. are used (ZrSiO_4). The opacifying effect of this is based on
 the co-existence of 2 phases having different refractive indices and solubilities.
 The opacification increases with increasing difference between the indices of the
 opacifier and glaze. The indices of normal glazes vary between 1.5 and 1.8, whereas
 the index of SnO_2 is 2.04, and that of Sb_2O_3 is 2.6; ZrSiO_4 has an index of 1.85.
 During melting, ZrSiO_4 releases ZrO_2 with an index of 2.4 (i.e. higher than that of
 SnO_2). Both SnO_2 and ZrO_2 dissolve in the glaze at the fusion temp., but separate
 out again during cooling. Another merit of ZrSiO_4 is its low coeff. of thermal
 expansion. Expts. have shown that the fritted glazes are considerably superior to
 raw ones of the same comp. The addition of 5–7% ZnO and 10–15% Al_2O_3 and a
 simultaneous reduction of SiO_2 improves the gloss and opacification. The best
 opacifying effect is achieved when 8–10% of ZrSiO_4 is added to the frit and 5–10%
 to the batch. The m.p. of the glaze is 950°–1,000° C., the coeff. of linear thermal
 expansion of its optimum comp. is 5.37×10^{-6} , the whiteness 82%, and the gloss
 75%. *B-Ti coloured opaque glazes*: As substitutes for Pb cpds., colemanite, hydro-
 boracite and "painter's Ti" were used. ZrSiO_4 , owing to its chem. inertness, is
 not suitable for bright colour shades; these frits were therefore used without ZrSiO_4
 with an increased content of B_2O_3 . This reduced the m.p. of frits to 1,000°–1,050° C.
 and of glazes to 940°–990° C. The latter had a low viscosity and a good gloss.
 On the basis of the above frits, by the addition to the mill batch of pigments and
 on-glaze colours (5–13%), a palette of glazes of various rich colours was obtained.
 The m.p. was 940°–1,000° C., the coeff. of linear thermal expansion 4.77×10^{-6} , and
 gloss 79%. *F glazes*: Preliminary expts. have shown that Na_2SiF_6 can be used as

Firing of fusible opaque zirconium glaze. S. G. Tumanov
and A. A. Nalbandyan. *Steklo i Keram.* 10, No. 1, 15-18
(1953).—Prolonged holding at 1000° improves the surface
and luster of boro-Zr glaze, but opacity and whiteness are
impaired. Prolonged holding during cooling impairs the
surface and causes crystals. Optimum heat cycle includes
holding at 1000° for 0.5-1 hr. and cooling in a short period
(up to 1 hr.). Microscopic study reveals that opacity is
caused by Zr, accumulation of fine-grained needle-like
crystals of unknown origin, and quartz. B. Z. Kamich

Lower limit of reaction between hydrogen and oxygen. A. BIRON and A. NALBANDIAN. (Acta Physicochim. U.R.S.S., 1937, 6, 43-66).—The lower limit (p) of ignition of H_2-O_2 (O_2 40%) mixtures in re-fused Pyrex vessels is not sensibly affected by the presence of A; thus confirming the theory of Kassel and Storch (A., 1935, 700). In SiO_2 vessels where p is considerably higher, addition of A diminishes p in proportion to the partial pressure of A, in accordance with the theory of Burian and Sorokin (A., 1931, 688). In both cases p is the partial pressure of $H_2 + O_2$. Experiments are recorded showing the relation between p and the % composition of A-free H_2-O_2 mixtures.

CA

Photochemical oxidation of hydrogen. I. A. H. Nalbandyan. *Acta Physicochim. U. R. S. S. R.* 11, 453-54 (1959) (in English).—The velocity of the photochem. oxidation of H at pressures of 1-50 mm. irradiated by light of 1300-1750 Å. is given by $w = (\pi J/\beta) \sqrt{d^2/(1 - e^{-k\alpha}) [1 - (-i)^{1/2}/\pi pd] (J_0(ix)/J_0'(ix))}$, where J = intensity of illumination, β = probability of chain rupture, d = diam. and l = length of reaction vessel, k = absorption coeff. for O, $\alpha = \sqrt{(3/4) \lambda \mu}$, $\lambda = \pi pd$, q = no. of collisions undergone by O₂ before reaction with H, and $J_0(ix)$, $J_0'(ix)$ are Bessel functions of 0 and 1st order. The mechanism of the zone formation process is: O₂ + h ν = O' + O; O + H₂ + M = H₂O + M (M = any mol.); O + O₂ + O₂ = O₃ + O₂; O + wall = 1/2 O₂. The probability of the reaction O + H is 10⁻⁶. The quantum yield is 2 moles. of H₂O + O₂ per quantum absorbed. N. believes that no chains are formed, but that both excited and normal atoms act as active centers.

Spontaneous ignition of $2H_2 + O_2$ mixtures in silver vessels.
A. B. Nalbandjan (*Compt. rend. Acad. Sci. U.R.S.S.*, 1941, **22**,
106-109) In examining the spontaneous ignition of $2H_2 + O_2$
mixtures in Ag vessels, the rapidity of the surface reaction makes
very rapid filling necessary, since ignition is inhibited by H_2O .
The lower limit of spontaneous ignition in the Ag vessel used de-
creased with increasing temp from 33 mm. at 67° to 17 mm. at
85°. The ignition has an induction period which decreases rapidly
with increasing pressure above the ignition limit, and at the limit
decreases with increasing temp. The shortness of the induction
period and the surface reaction prevent the upper limit from being
determined. L. J. J.

I. Dependence of Induction Period on Pressure and Temperature, II. Influence of
Admixtures," Acta. Phys., No. 6, 1944₂

NALBANDYAN, A. B.

The kinetics of hydrogen oxidation in the region of low-temperature ignition. I. Dependence of induction period on pressure and temperature. A. B. Nalbandyan. *Acta Physicochim. U.R.S.S.* 19, 483-500 (1944) (in English). —Based on the mechanism of H oxidation suggested by Lewis and Elbe (*Combustion Flames and Explosion of Gases*, Cambridge, 1934) and on Semenov's method of partial stationary concn. (*Chemical Kinetics and Chain Reactions*, C.A. 29, 1706'), a formula for the dependence of the induction period upon pressure and temp. inside the peninsula of low-temp. ignition of $2H_2 + O_2$ was derived. Expt. shows this formula to be well satisfied on ascribing the value 23,000 cal. to the activation energy of the chain-branching reaction $H + O_2 = OH + O$, which ultimately detcs. the over-all reaction rate as well as the temp. dependence of the upper limit. The rate of H oxidation was investigated as a function of the compn. of the mixt. Expt. and theory are shown to be in complete agreement. II. Effect of admixtures. *Ibid.* 407-507. —The effect of water and I_2 on the explosion limits and the kinetics of H oxidation within the region of low-temp. ignition were investigated. H_2O vapor is shown to lower the upper limit and to displace the ignition peninsula towards higher temps. H_2O is further shown to act on the upper limit as an inert gas, its efficiency being six times as large as that of I_2 , and to have no effect on the temp. dependence of the parameter ϕ characterizing the velocity of H oxidation. Traces of I_2 in the H-O mixt. greatly lower

the upper explosion limit, shifting the region of self-ignition towards higher temps., and affect the kinetics of $2H_2 + O_2$ ignition. In contrast to H_2O , I_2 mols. exert a direct action on the branching reaction $H + O_2 = OH + O$, resulting in changes in the temp. dependence of ϕ .

Explosion limits of an explosive mixture of hydrogen and oxygen in an iron vessel. A. B. Naibandjan (*Compt. rend. Acad. Sci. U.R.S.S.*, 1944, **44**, 328-330).—The upper pressure limit of an explosive mixture of $2H_2 + O_2$ determined in an Fe vessel is the same as in a SiO_2 vessel. On the other hand, the lower pressure limit in an Fe vessel is $>$ in SiO_2 . This suggests that the active centres of the reaction recombine more easily on metallic than on non-metallic surfaces. The temp.-dependence of the lower limit is given by $P_{lim} = \frac{E}{RT}$, where $E = 9-10$ kg.-cal. C. R. H.

Kinetics of hydrogen oxidation in the region of low-temperature ignition. III. Influence of vessel material. A. Nalbandjan (*Acta Physicochim. U.R.S.S.*, 1945, 20, 31-34).—Experimental data for the kinetics of oxidation of H_2 in a Durabax vessel washed with a solution of KCl and in a stainless steel vessel do not indicate any dependence of reaction rates on the condition of the vessel walls. The increase of the lower limiting pressure in the former case is accounted for by assuming the probability of destruction of the active centres on the walls of a vessel covered with a layer of KCl to be > the probability of destruction on clean walls. <p>Explosive properties of "gasless" systems. A. P. Belyayev and A. B. Nalbandyan. <i>Comp. rend. acad. sci. U.R.S.S.</i> 46, 107-9(1945); <i>Doklady Akad. Nauk S.S.S.R.</i> 46, 113-16(1945).—The specific effect of the volume of the gaseous or vaporous products of an explosive reaction on the rate of detonation was investigated. A series of experiments were performed with each of 8 explosive mixtures which had gaseous products in neither the initial nor final stages: (1) $3AKClO_4 + FeSi_2 = 3KCl + 0.5Fe_2O_3 + 4.65SiO_2$, and (2) $KClO_4 + 2Al = KCl + Al_2O_3$. The explosive energies of the two "gasless" mixtures were detd. by measuring the compressions of a lead column obtained by employing a modified Hess method and a No. 8 capsule detonator. In 3 runs using the "gasless" mixture $KClO_4 + FeSi_2$, the diameter of charge, wt. of charge in g., and compression of the lead column in mm. were, by resp.: 40, 80, 0; 58, 240, 0.7; and 77.5, 480, 15.1. Using the system $KClO_4 + Al$ for the same diameters and weights of charge as above and a mixture density of 0.95 g./cc. as compared with 0.54 above, the respective compressions of the lead column were 5.40, 16.73, and 21.55 mm., resp. The $KClO_4$ and Al mixture gives a relatively big acoustic report. With 50 g. of the "gasless" mixture of $KClO_4$ and Al a compression of 18.40 mm. is obtained as compared with 18.0 mm. produced by the same quantity of the mixture $KClO_4$ and peat, which yields 40 l. of gaseous products. Experiments to determine the stability of the detonation and its velocity were carried out in tubes of different diameters. In the case of both gasless mixtures, the detonation was stable when tubes greater than 16 mm. in diam. were used. For the $KClO_4$ and $FeSi_2$ mixt. the detonation velocity measured by the Drautriche method in a tube 20 mm. in diam. was 1170 m./sec.; in a tube 27 mm. in diam., 1270 m./sec.; for the $KClO_4$ and Al mixt. the detonation velocity in a tube 21 mm. in diam. was 1300 m./sec., and in a tube 40 mm. in diam., 1370 m./sec. Expts. to det. the vol. of gaseous explosion products for the $KClO_4$ and Al system were made in a metal bomb in which a pressed lead azide detonator was used which was set off electrically. The gaseous vol. was found to be significant, and was found to comprise 45% carbon-oxygen compds. However, since a considerable part of the explosion work of both gasless systems is expended at a temp. much higher than the critical for KCl, it follows that this substance should be in the vapor state during a considerable portion of the explosion process and consequently behave like a gas. Even this vol. of vapor is small compared to that given off by the usual explosives. All attempts to produce stable detonation in systems yielding neither gas nor vapors even at high temps were futile. J. Findlay</p>

Experimental determination of the probability of the disappearance of active centers. A. U. Nalbandyan (Inst. of Chem. Physics, Acad. of Sci., U.S.S.R.). *Compt. rend. acad. sci. U.R.S.S.* 47, 202 3(1948); *Doklady Akad. Nauk S.S.S.R.* 47, 208 3(1948). — The introduction of pieces of metal wire into glass or quartz vessels markedly raises the lower ignition limit of combustible mixts. The expression developed by Semenov (*C.A.* 38, 3180'), $(pd)' = 4B/\ln(d/\Delta)$, where p is the pressure at the lower limit of combustion, d is the diam. of the reaction vessel, Δ the diam. of the wire, and B a const. depending on the temp., was confirmed for the mixt. 211, plus O_2 at 404°. The lower limit of ignition in mm. of Hg without a wire was 0.05 mm.; for wire of diam. 0.2 cm., 4.20 mm.; 0.1 cm., 3.80 mm.; 0.015 cm., 3.10 mm. H. G. McCann

✓ NALBANDYAN, A. B.

Measurement of the coefficient of recombination of atomic hydrogen at various surfaces by a determination of the lower limit of ignition of the mixture $2H_2 + O_2$. A. B. Nalbandyan and S. M. Shubina (Inst. Chem. Phys., Acad. Sci. U.S.S.R., Moscow). *J. Phys. Chem. (U.S.S.R.)* 20, 1249-53 (1946) (in Russian).--The lowest total pressure p at which the mixt. $2H_2 + O_2$ can be ignited at 440° is 1.05 and 7 mm. Hg in glass vessels of 6.50 and 1.83 cm. diam. Filaments of other solids, 0.05-0.1 cm. in diam., raise p . The greatest increase was observed with $ZnCr_2O_4$ and graphite; both give $p = 10.3$ mm. in a vessel that, alone, gave $p = 0.53$ at 400° . Au, W, Pt, and stainless steel show smaller increases of p . Untreated quartz raised p at 440° from 0.04 to 2.34, and quartz rinsed with HF raised p to 1.18. KCl did not affect p at 500° because of rapid evapn. Pd and (above 390°) Pt catalyzed the combustion of H_2 so that p could not be measured. From the exptl. p values the coeff. ϵ of recombination of H atoms at various surfaces can be calcd.

$ZnCr_2O_4$ and graphite have $\epsilon = 1.0$ at 490° , Au 0.0018 at 440° , Pt 0.0085 at 388° , W 0.0057 at 540° , stainless steel 0.0028 at 440° , untreated quartz 0.0005 at 440° , quartz rinsed with HF 0.0003 at 440° , and pyrex glass washed with a $K_2B_4O_7$ soln. 0.00002 at 440° . The pressure p in the presence of graphite was detd. also at 530° and 558° ; from these values the energy of activation of the reaction $H + O_2 = OH + O$ appears to be 17,800 cal. From the increase of the upper limit of ignition with temp. between 310° and 410° in a glass vessel washed with $K_2B_4O_7$ soln. the activation energy of 18,000 cal. is computed. All the above results agree with Semenov's theory (*C.A.* 38, 3189').
