TITLE: Method of obtaining a hard gold-nickel alloy electrolytically

SOURCE: Metalurgia, no. 9, 1966, 508-510

TOPIC TAGS: electrolysis, electroplating, electrolyte, alloy, gold base alloy, microhardness, gold nickel alloy, aurocyanite, nickel sulfate

ABSTRACT: Preliminary experimentation to obtain a hard gold-nickel alloy followed procedures described in 9 foreign patents. The purpose of the experiments was to study gloss, hardness, deposit adhesion properties, and electric current yield. After a number of tests, a new electrolyte of good quality was developed with the following composition and operational characteristics: gold in the form of $K[Au(CN)_2]$ -aurocyanide, 4 g/l; nickel, as nickel sulfate ($NiSO_4$), 3 g/l; disodium phosphate, 40 g/l; sodium (potassium) citrate,

ACC NR: AP7004499

40 g/l; citric acid, 20 g/l; pH, 4—5.5; cathode current density 1—1.5 ampere/dm; and working temperature 18—24 C. Electrolysis takes place at 40—50 C, with an anode current density of 1—1.65 ampere/dm². The gold-nickel deposit with a 2—2.5 percent nickel content has a high gloss, obtained after one hour of electrolysis, good adhesion, and a higher hardness than that in similar alloys. Microhardness amounts to 160—180 kgf/mm², as compared with the 90—100 kgf/mm² in pure gold achieved electrochemically. Advantages of the new method, which is already being used in an electroplating shop at the "Electromagnetica" Plant in Bucharest, are operation at room temperature; relatively high current densities; high gloss of deposits even after prolonged electroplating; little change in deposit composition and quality due to electrolyte variation; and use of inexpensive and easily available nickel sulfate. TITLE: Nonlinear current-voltage characteristics of thermal origin

SOURCE: Physica status solidi, v. 8, no. 3, 1965, 881-896

TOPIC TAGS: semiconductor, photoconductivity, dielectric material, thermoelectric property, current voltage diagram, cadmium sulfide crystal, phosphorus doped silicon

ABSTRACT: Studies were undertaken to establish the conditions under which thermally initiated, negative, differential N- or S- type resistances (tension- or current-controlled) develop in semiconductors, photoconductors, or dielectric substances, and to establish under what conditions such resistances of the N-S type occur under conditions of nonlinear temperature-dependence. These studies involved the theoretical calculation and experimental determination of the current-voltage characteristics of various types of substances while their temperature was increased by Joule heating. In the cases where the temperature-dependence of the electrical conductivity was nonlinear, N-S type negative differential resistances occurred. Typical nonlinear curves, showing the temperature vs. resistance be-

4
havior of a CdS crystal and of phosphorus-doped silicon, respectively, are presented in Figures 1 and 2 of the Enclosure. It was indicated that spontaneous changes in current during the determination of the current-voltage characteristics without the use of a stabilizing resistance would represent thermally initiated phenomena. Thermally induced, negative, differential resistances of the N-S type may also develop under conditions of homogeneous field strength and current density. The thermally induced $dU/dI < 0$ (where U represents voltage and I represents intensity) zone is surrounded on both sides by zones of positive differential resistance in case of the N-type but not in case of the S-type. "We thank Dr. E. Gutsche for valuable discussions and for a critical review of the manuscript, and Dr. U. Kummel for considerable advice." Orig. art. has: 20 formulas and 8 figures.

TITLE Flocculating Suspended Matter by Means of Polyelectrolytes
(Agregatsiya suspenziy polielektrolitami)

PERIODICAL Byul. tsvetn. metallurgii, 1957, No. 17, pp. 13-14

ABSTRACT An analysis of data taken from the literature and of experimental data led to the conclusion that one of the most important ways of accelerating thickening was through the action on the pulp of chemical substances capable of flocculating the solid pulp particles. Most effective were polymers of certain specially treated compounds, namely, polyelectrolytes.

TITLE: Application of Polyacrilamide^A in thickening of Scheelite Concentrates

PERIODICAL: Tsvetnyye metally, 1960, Nr. 2, pp. 17-20 (USSR)

ABSTRACT: In continuation of work carried out at the Institute of Non-Ferrous Metals (Ref. 4, 6, 7), the authors of the present paper have conducted a series of experiments in improving the efficiency of the thickening operations with the aid of polyacrilamide, which is generally regarded as a very good flocculating agent. The products used in these experiments had been prepared in a pilot plant at the Leningrad Metallurgical Research Institute by polymerization of the products of hydrolysis of acrylonitril with sulphuric acid, the colourless gelatinous mass obtained in this manner contained 5% of active polyacrilamide). The experiments were conducted on beneficiation products obtained at the Ingushkinsky Plant, the ore, treated at this plant at the time of the present investigation, contained 0.3 to 0.6 WO₃ in the form of scheelite, finely dispersed in pyroxenes and

Application of Polyacrylamide in Thickening of Scheelite Concentrates

pyroxene garnet skarns, and up to 15% of gangue minerals (granite and lime-stone). The ore was ground to contain 55 to 60% of the -0.074 mm fraction) in the presence of sodium carbonate (approximately 4.5 kg/t) pH of the pulp being maintained at 9.7 to 10.0; prior to flotation, the pulp was treated with sodium silicate (1.5 kg/t), after which oleic acid (0.27 kg/t) mixed with equal quantity of kerosene, was added. The roughing flotation yielded concentrate in the form of pulp (23 to 24% solids) containing 2 to 4% WO_3 , which was fed into an 8 m thickener. The slime discharge from the thickener (which was discarded) contained 50 to 60 g of solids per litre, the WO_3 content in these solids being 0.6 to 0.8%, i.e. higher than in the concentrate. To avoid these losses of scheelite, the slime discharge from the thickener was, for some time, returned to the flotation machine; this step, however, failed to produce the desired results, owing to the fact that scheelite can be successfully floated only directly after being conditioned with the flotation reagents and losses its

Application of Polyacrylamide in Thickening of Scheelite Concentrates

floatability after being circulated. For this reason, scheelite present in the slime discharge was not recovered and was lost in the flotation tailings. Apart from the fact that the flotation process itself was adversely affected by the introduction of the slime discharge into the feed. The crude scheelite concentrate like the sand discharge from the thickeners mixed with sodium silicate (5.5 kg/t) was steam-heated at 85 to 90°C and fed into the flotation machine at the beneficiating cycle. The final flotation concentrate contained 55 to 60% WO_3 , constituted a pulp with about 40% solids and was thickened in four pyramidal flotation tanks (total area = 12 m², total volume = 15 m³). The slime discharge from these tanks, containing 5 to 65 g/l of solids with 6 to 12% WO_3 , was treated again in a cylindrical settling tank in series with several separate settling tanks (total area = 12 m², total volume = 12 m³) however, only 10% solids was recovered by this method so that in each 15 m³ of the slime discharge, 500 kg

Application of Polyacrylamide in Thickening of Sulfite
Concentrates

the pulp became absolutely clear after 5 to 6 min settling. For rapid measurement of the transparency of the liquid, a photosexonimeter of the "Leningrad" type was used. It had been roughly calibrated by determining the position of the pointer for pure water (fifth division on the scale) and for water containing more than 20 g/l solids (second division on the scale), and the relative transparency of the clarified portion of the pulp in various experiments was described by quoting the reading of the instrument. This method was used in presenting the results of experiments in which the effect of the method of adding 50 g/t of polyacrylamide to the rough concentrate on the settling process had been studied. These results are reproduced in Table 1 under the following headings: settling time, min.; transparency of the clarified portion of the liquid when the flocculant, in the form of an 0.5% solution, had been added in six doses; transparency of the clarified liquid when the flocculant, in the form of an 0.10% solution, was added in ten doses. It will be

seen that if a low consumption of the flocculant is aimed at, it may be used in a highly diluted form. Thus, for instance, when only 30 g/l of the reagent is used, it should be diluted to 0.003%. Similar results were obtained for settling of the final concentrate in the case of which 25 g/l of the flocculant, diluted to 0.003% gave satisfactory results, although, when further dilution was attempted, no flocculation took place unless more reagent was used. The laboratory investigation was followed by a series of industrial tests in which polyacrylamide was used. The flocculant was fed continuously for 30 hours, the same in general. The specific consumption of the reagent was calculated from the data on the quantity of the treated ore and the quantity of flocculant used during this period. When no flocculant was applied, the slime discharge of the thickener contained 50 to 67 g/l solids. In the presence of the flocculant, the content of solids in the slime discharge was reduced to 12 to 20 g/l, the corresponding consumption of the flocculant being 90 to 30 g/t. In

Application of Polyacrylamide in the Treatment of Selenite Concentrates

this way, the content of solids in the sludge discharge from the thickener was reduced by more than 75% giving a daily saving of 3.5 to 6 tons of valuable material. Some results of the industrial tests are reproduced in Table 2 under the following headings: (conditions, no flocculant, no flocculant, flocculant added, flocculant added, shift, content (%) of WO_3 in the ore tailings, and rough flotation concentrate, recovery (%) of WO_3 in the rough concentrate, WO_3 content (%) in the final concentrate. The effect of the polyacrylamide addition on thickening of the treat concentrate was even more beneficial since, in this case, it was possible to obtain a larger proportion of this reagent in the absence of the flocculating agent. The clarified part of the ore settling contained 60 g/l solids when polyacrylamide was added (30 l of 0.5% solution per 1000 l of concentrate) and the clarified part without settling contained 170 g/l of suspended solids. It was estimated that 15-20% of the flocculant were used per unit of the

TITLE: Paramagnetic resonance on conduction electrons of copper

PERIODICAL: Doklady Akademii nauk SSSR, v. 137, no. 3, 1961, 549-550

TEXT: This paper was read at the XIII Vsesoyuznoye soveshchaniye po spektroskopii (XIII All-Union Conference on Spectroscopy) held in June, 1960. Experiments are described of studying the surface resistance of copper in a magnetic field H for frequencies up to $\nu = 3.6 \cdot 10^{10}$ cps. The purpose of the experiments was to observe the paramagnetic resonance. The specimen was a copper resonator (wave guide) made of pure electrolytic copper having the ratio $R_{4.2^\circ K} / R_{300^\circ K}$ less than 10^{-3} . This value rose to 10^{-2} due to Cu deformation during the construction of the resonator

The surface of the resonator was polished electrolytically. Fig. 1 shows graphically the values $R(H)/R(0)$ as a function of the magnetic field strength at temperatures of $77^\circ K$ and $4.2^\circ K$. From the value of the field strength for the maximum, the value of the g factor is determined

to be about 2.1. It is found that the form of the absorption line depends essentially on the temperature; that the intensity of the line with the g -factor 2.1 increases with a decrease in temperature, the blurred lines broadening simultaneously and disappearing completely at the temperature of helium. To clarify the nature of observed lines the temperature dependence of the intensity of these lines and the absorption lines of the radical were studied. The experiments showed that the line intensity of the radical decreases to a quarter of its value as the temperature was increased from 77 to 300°K, while that of the absorption line of the resonator remains practically constant. With the help of Dyson's theory the authors conclude that the lines with $g = 2.1$ are related to the spin relaxation of the conduction electrons. The contraction of these lines on change of temperature is related to the increase of the spin relaxation time: $1.7 \cdot 10^{-10}$ seconds at 300°K; $2.1 \cdot 10^{-10}$ seconds at 77°K;

$4.2 \cdot 10^{-10}$ seconds at 4.2°K. The broadening of the second absorption line is caused by the decrease of the electron diffusion time from the skin layer into the metal. Furthermore, the experiment showed symmetric absorption lines which fact is in contradiction with the results of the

theory. This is because the conditions in the experiment are different from those assumed in the derivation of the theoretical law. Professor D. P. Zosimovich is thanked for making available a very pure copper foil prepared in the laboratory of the Institut neorganicheskoy khimii AN USSR (Institute of Inorganic Chemistry of the Academy of Sciences UkrSSR). There are 1 figure and 10 references: 2 Soviet-bloc and 8 non-Soviet-bloc.

TITLE A Graphical Method for the Analysis of Transitional Motions of the Engines-Propellers-Hull System of a Ship (Graficheskiy metod analiza perekhodnykh dvizheniy sistemy dvigatelya - vinty - korpus sudna)

PERIODICAL Nauch tr Odessk in-t inzh mor flota, 1956, Nr 12, pp 38-51

ABSTRACT In the examination of the main powerplant of a ship in conjunction with the propellers and the hull of the ship as a single mechanical entity, the investigation of the comportment of the entire aggregate must be based on a simultaneous solution of the equations of motion of the engines, the propellers, and the ship itself. Such an investigation becomes exceedingly difficult if it is conducted by the usual analytical and graphical methods employed in the theory of machines. Therefore, the author proposes a graphical method for the analysis of the comportment of propeller-driving ship powerplants, wherein the characteristics of the ship hull and the propellers are assumed to be

Card 1/2

A Graphical Method for the Analysis of (cont.)

given and the drive torque is assumed to be a function of the angular shaft speed. This method affords a solution of the equation of motion of the system during transitional phases, such as during acceleration, halting, and reversal of the motion of the ship and the engine-propeller group, in the transition of the entire system from one regime to another, and permits the determination of the indispensable parameters of such a motion, such as the relative velocity of motion of the ship, the variation of the angular velocity of the propeller with time, the duration of a coasting run-out, etc. An illustrative example accompanies the paper.

TITLE A Recording Instrument Registering the Motion of Ship Engines During Transitional Stages of Operation (Pribor dlya registratsii dviizheniya sudovyykh dvizhatel'nykh agregatov)

PERIODICAL "Nauchno-tekhnicheskaya informatsiya" 1965, No. 12, pp. 59-60

ABSTRACT A description of the operating principle and design of a tachograph—a special instrument intended to determine the ship by the coasting method, as well as for the control of the maneuvering operations of the ship engines, in different operating conditions. The analysis of the tachograms obtained by means of the described instrument permits to establish the performance characteristics of an engine as well as its rpm versus time. The instrument may also be used as a mathematical device, having the combined functions of both a cycloidograph and an elipsograph.

Dinamika mashin, obrabotki statiki (Dynamics of Machines. Collection of Articles) Moscow, Mashgiz, 1960. 280 p. (Its title page slip marked. 3,000 copies printed.)

Sponsoring Agency: Institut mashinovedeniya i kuznetsovskii otdel.

Editorial Board: I. I. Arkobolevskiy (Resp. Ed.) Academician, Doctor of Technical Sciences, Professor, O. G. Baranov, Doctor of Technical Sciences, Professor, A. P. Bessonov, Candidate of Technical Sciences, Professor, V. A. Gavrilenzkiy, Doctor of Technical Sciences, Professor, A. N. Gubinskiy, Doctor of Technical Sciences, Professor, L. M. Maslov, Doctor of Technical Sciences, Professor.

Ed.: L. V. Buzinovskiy, Candidate of Technical Sciences, Associate Ed. for General Technical Literature and Literature on Transport Machine Building (Mashgiz).

A. P. Galov, Engineer, Tech. Ed. B. I. Kozlovskiy, Engineer, Tech. Ed.

REMARKS: This collection of articles is intended for engineers, designers, workers at scientific research institutes, and instructors at schools of higher technical education.

COVERAGE: This collection consists of reports presented at the All-Union Conference on Problems in the Theory of Machines and Mechanisms held in Moscow in 1978. The reports discuss theoretical problems of the dynamic behavior of complex mechanical systems. No particular attention is given to the design of machines and mechanisms. References accompany most of the articles.

Problems of coordinating the operation of the engines, propellers, and the hull of a ship; research with the aid of an electronic analog computer (Voprosy sovместnoy raboty dvigateley, vintov i korpusa sudna; issledovaniye na EVMND) Leningrad, Izd-vo "Sudstroyeniye," 1965. 246 p. illus., biblio., 2400 copies printed.

TOPIC TAGS: marine engineering, marine engine, marine equipment, ship component, computer modeling

PURPOSE AND COVERAGE: This book is intended for engineers and mechanics engaged in the research and design of ships. It may also be useful to students in schools of higher education. The problems of coordinating the operation of all of the ship's components during the transition processes in maneuvering are covered. Sets of equations, characterizing the movement of the various ship components, are presented and criteria for comparison of various engine, propeller, and hull combinations are given. The nomograms of the calculated results may be used in the design and construction of ships. Methods of using computers to solve the complex problems of the dynamics of the ship's systems during the reversing process are also covered, and solutions for the computations of these problems for all types of ship systems are presented in charts.

TITLE: The performance of marine engines under storm conditions

SOURCE: Nikolayev. Korablestroitel'nyy institut. Sudostroyeniye i morskoye sooruzheniye no. 3, 1966, Sudovyye energeticheskiye ustanovki (Ship power equipment), 63-67

TOPIC TAGS: ship component, marine engine, engine performance characteristic, shaft, elasticity

ABSTRACT: The dynamics of ship propulsion units with elastic coupling between the main engine and the screw was investigated analytically for storm conditions. The equations of motion of the system elements were taken in the standard form. The change of the relative torque of the elastic coupling was represented by the mechanical characteristics of a single-cell electromagnetic slip clutch. This approximates the characteristics of marine hydrodynamic clutches. The effects of the rocking motion of the ship were introduced in accordance with the findings of M. A. Grechin (O sovmeystnoy rabote grebnogo vinta i dvigatelya v usloviyakh volneniya i kilevoy kachki sudna. Trudy TSNIMFa, vol. 35, 1961). Since the equations can not be solved

in a closed form, an analog computer was used to produce a solution which is presented on an oscillograph as functional relationships between the shaft speeds for the various components and the ship motion. The physical parameters introduced in the computer cover the entire range of practical values. Orig. art. has: 2 figures and 7 formilas.

TITLE: Dynamic analysis of hydromechanical complexes of hydrofoils by means of analog computers

SOURCE: Ref. zn. Vodnyy transport, Abs. 10V50

REF SOURCE: Sb. Vyhisl. tekhn. na morsk. transp. M., Transport, 1966, 76-87

TOPIC TAGS: hydrofoil, function analysis, mathematic analysis, analog computer

ABSTRACT: Theoretical methods of studying hydrofoils under transition operating conditions, such as the maneuvering properties of their main engine, power transmission, propeller, and hull system, and particularly of the composite hydromechanical complexes of hydrofoils, can be obtained only by means of analog computers. Such a system is investigated in the following consecutive order: plotting of the mathematical reference description of the system processes; reduction of equations to a general form; solving of transformations with analog computers; plotting of diagrams or approximate analytical relations. A mathematical description of the transition operating conditions of hydrofoil hydromechanical complexes with constant-pitch propellers is presented. The obtained equations are of a form adequate for easy use on analog computers.

Mekhanizatsiya i industrializatsiya elektromontaznykh rabot (Mechanization
and Industrialization in Electrical Assembly Work) Moscow, Gosstroyizdat,
1949. 218 p. 5,000 copies printed.

Ed. of Publishing House: G. M. Shirokova; Tech. Ed.: L. M. Osenko.

PURPOSE: This book is intended for technical personnel engaged in electrical as-
sembly work.

COVERAGE: The book presents the fundamentals of installation practices of power-
generating and distributing equipment. Devices used in the installation jobs
and problems of mechanization are surveyed. Methods applied to such
operations are described and evaluated. The material presented in this book
reflects the most advanced practices as applied, for example, by the Glavelektro-
montazh (Main Administration for Power-Equipment Installation) of the Ministry
for Civil Engineering and Industrial Construction of the RSFSR and by the
