"The Influence of Large-Scale Turbulence Upon the Propagation of Sound in a Turbulent Medium," M. G. Odintsov, I. G. Shaposhnikov, Physicotech Inst, Kazan Affiliate, Acad Sci USSR, 8 pp

"Zhur Tekh Fiz" Vol XIX, No 9

Blokhintsev's equations are used for discussion. Considers case of a stationary acoustic field, created by a source not having directivity, and a stationary homogeneous isotropic field of turbulent pulsations imposed on the averaged flow. By considering velocity of motion of the medium

to be low compared with velocity of sound and by disregarding compressibility of the medium, authors found an expression for mean (with respect to time) square of deviation of the value characterizing intensity of sound due to turbulence from the value which it would have in a quiescent medium. This square of turbulent fluctuation of sound audibility increases with the third order of distance from source and decreases when wave length of sound increases. Authors state that both this work and Krasil'nikov's are incomplete because precise form for correlation function for a flat-topped field of large-scale pulsations is not known. Submitted 10 Jul 48.

ABSTRACT: The authors describe apparatus for obtaining an exact delay of a reference pulse. The arriving reference pulse triggers a scaler device, to which pulses from a quartz generator are fed. After counting a specified number of pulses, the selection circuit produces an output pulse. Such a method makes it possible to obtain a delay accuracy of +0.005%. The apparatus described produces in each channel a delay of 0 - 100 msec in discrete steps of 10 μ sec. The instrument is constructed of semiconductor diodes and transistors, using printed wiring. V. SOURCE: Physica status solidi, v. 19, no.1, 1967, 407-415

TOPIC TAGS: ion emission, electron emission, ion electron emission, incidence angle

ABSTRACT: A study was made of the dependence of the coefficient of ion-electron emission on the angle of incidence of a graphite target and polycrystalline metal (Cu, Ag, Mo, Zr, W, Bi) targets, bombarded with inert gas and nitrogen ions at 25--30 kev. The application of a magnetic field parallel to the axis of rotation shows that both the positive and negative ion currents to the collector are negligibly small. The emission coefficient increases with an increase in the angle of incidence

TITLE: Effect of thermal fluctuations in a crystal lattice on the coefficient of ion-electron emission

SOURCE: Fizika tverdogo tela, v. 8, no. 10, 1966, 2934-2944

TOPIC TAGS: crystal, crystal lattice, ion emission, electron emission, monocrystal, polycrystal, copper

ABSTRACT: The dependence of the coefficient of ion-electron emission γ on the angle of incidence ϕ of ions on a target at 200 and 900C was investigated for various orientations of a copper monocrystal and for a polycrystal copper target under bombardment by $^{20}\text{Ne}^+$, $^{40}\text{Ar}^+$, $^{84}\text{Kr}^+$ ions with an energy of 30 keV. The polycrystal target was found to have an almost constant value at different target temperatures (at the same angle of ion incidence on the target). An increase in monocrystal target temperature results in a smoothing out of anisotropy in the coefficient of emission. Furthermore, the change in the form

TITLE: Ion-electron emission of single crystals as a function of target temperature

SOURCE: AN SSSR. Doklady, v. 162, no. ⁴⁴¹⁵⁵ 4, 1965, 778-780

TOPIC TAGS: copper, single crystal, secondary electron emission, ion bombardment

ABSTRACT: A method is proposed for calculating the effect which the thermal motion of atoms has on electron emission from a single crystal target bombarded by ions. A formula is derived for the average energy imparted by the first collision of an ion with the atoms of the target. The method proposed in this paper is used in conjunction with a previously derived formula (Ye. S. Mashkova, V. A. Molchanov, D. D. Odintsov, *DAN*, 151, 1074, 1963) to calculate the coefficient of ion-electron emission γ for a copper single crystal target bombarded by 30 kev argon ions. The theoretical curves agree well with experimental data. The effect of variations in temperature on the angular relationships of ion-electron emission in this case is apparently due mainly to changes in the transparency of the crystal (i. e. the probability of the first collision of an ion with atoms of the crystal) rather than

target were attracted by the collector before which a grid was placed to suppress "tertiary" electrons emitted by the collector. The experiment measured the ion current I_0 and current I_1 , the latter being the sum of the ion current and the current of secondary-emission particles. The ion-electron emission factor was determined as the ratio of secondary current to the ion current. It was shown that the dependence of the emission factor on the incidence angle is nonmonotonic and that the number of emitted electrons decreases sharply whenever the direction of the primary beam coincided with a main crystal axis of the target. Calculations show that collisions with atoms of the first few layers alone are of substantial significance in electron emission and that the dependence of the number of electrons emitted upon the angle of incidence corresponds to the variation of collision probability. "The authors thank N. I. Zakharov for aid in conducting the experiment." Orig. art. has: 3 figures and 2 formulas.

TITLE: The dependence of single crystal sputtering on the direction of the incident particles

PERIODICALS: Fizika tverdogo tela, v. 5, no. 4, 1963, 1114 - 1116

TEXT: A semi-empirical formula for the sputtering coefficient S (ratio between the numbers of sputtered target atoms and incident particles) is derived and compared with experimental data. S is assumed to be proportional, in first approximation, to the energy transferred from projectile to target particles in the first collisions (Physica, 26, 1009, 1960). The collisions are considered as collisions between elastic spheres. The resulting relation reads

$$S = \frac{1}{A_0 \cos \theta} \left[\alpha_1 \epsilon^2 R^2 \frac{E_{max}}{2} + \alpha_2 S_2 E_2 + \alpha_3 S_3 E_3 + \dots \right] \quad (3)$$

here A_0 is a chosen unit area, not necessarily corresponding to the surface, E_i the energy of the primary atoms in the i -th plane, α_i the proportionality

SOURCE: Yadernyye reaktsii pri mal'kikh i srednikh energiyyakh; trudy Vtoroy Vsesoyuznoy Konferentsii, Iyul' 1960 g. Ed. by A. S. Davydov and others. Moscow, Izd-vo AN SSSR, 1962, 161-165

TEXT: Yu. A. Aleksandrov (ZhETF, 31, 726, 1956; 32, 154, 1957; 33, 294, 1957) has observed that on fast neutron scattering through small angles ($3-5^\circ$) a discrepancy arises between a cross section measured and as calculated, when Schwinger interaction is taken into account. The small-angle anomaly might be due to effects of neutron polarization in the nuclear Coulomb field. In order to find out whether there also are other processes participating, the present authors analyze the fundamental possibilities of the following particular effects: (1) interference between spin-orbital and Schwinger interactions, this effect estimated in Born approximation; (2) excitation of the atom due to interaction of the neutron magnetic moment with the electric field of the electron; (3) the presence of several possible intermediate states between initial and final state; (4) spin-independent

the rolls by the photoelasticity method,²⁶ a method which consists in that the load-caused change in optical properties at points in a model of an optically translucent material may be measured and expressed in quantities mathematically associated with the stress. This method was used to investigate single- and double-groove roll models constructed of an optically active material based on the ED-6 epoxy resin and built and stressed in accordance with the conditions of geometric and stress similarity. Findings: an analysis of the cross-sectional distribution of stresses in the rolls indicates that points along the contour are subject to the highest stresses. A comparison of the curves of contour stresses for single- and double-groove rolls shows that the maximum tensile stresses in the single-groove roll are roughly 20% higher than in the identically loaded double-groove roll. Therefore, the double-groove roll may withstand higher loads. Therefore also, the replacement of the single-groove rolls with double-groove rolls is, from the standpoint of roll strength, definitely feasible and does not lead to an increase in the stressed state of the roll given the same working load. Orig. art. has: 5 figures, 2 formulas.

ABSTRACT: The conversion of the currently operating cold-rolling tube mills to twin-groove operation makes it possible to increase their productivity by 50-75%. However, the simultaneous rolling of two tubes greatly increases the working load on the elements and components of the mill. This raises the question of assuring the operating reliability and strength of the rolls in these conditions. To resolve this question, the authors investigated the stressed state of

a noticeable increase of mineralization of subsoil waters and salted soils, mainly owing to the increase of general alkalinity. With regular irrigation, a rise of subsoil waters and an intensive salt accumulation in the upper levels of soils was observed. Thus, with bedding of subsoil waters to the depth of 0.5 m from the surface, the quantity of HCO_3 ions in farmed light chestnut soil increased over 6 years from 290 to 441, of Cl ions - from 240 to 868, and of SO_4 ions - from 810 to 2538 mg. per 1 kilogram of soil in the 0-20 cm. horizon. The sowing of grasses occasioned a noticeable decrease of the quantity of salts in the 0-50 cm soil horizon. After the organization of drainage (1942), a gradual process of salting of the soils began, and in 1953 the saltiness of

each other on a heavy bench. Radiation from 1 is attenuated by neutral filters by 10^4 or 10^3 times to provide a bypass from 1 to 2 and to avoid amplifier saturation. Lens 5 is used to produce coincidence of the wavefront, incident on 2, with the input mirror surface. The ratio of partial pressures of He and Ne in the amplifier is 17:1, resulting in a weak dependence of gain and activity of the medium on variations in the discharge current. The maximum gain of the system, measured in terms of the magnitude of the output signal from the amplifier when the oscillator frequency and the center of the amplifier passband are coincident, is 1000 (30 db). The misalignment of the amplifier axis with the direction of the incident wave, which affects gain, was not more than 3 sec of arc. The values of gain observed experimentally (mirrors: 99 and 98% reflective) and theoretically (mirrors: ideal dielectric) are in good agreement. Orig. art. has: 1 formula and 3 figures. [YK]

ABSTRACT: An investigation of the extent to which disruption of ideal alignment of a laser resonator mirror system influences the properties, primarily the output power, of the oscillation. A neon-helium laser generating in the visible light at 6328A was investigated. The experimental setup consisted of a laser, a device for measuring small inclination angles of the mirror, a vacuum system and a power supply. The discharge tube of the laser was 4 millimeters in diameter and 88 centimeters long. The generator power as a function of inclination of one of the mirrors was investigated with various lengths of laser resonator. The least length was 133 centimeters. It was determined that the requirements for alignment of mirrors in a laser with spherical mirrors varies considerably. In the case of generation of many transverse types of oscillation, considerable (up to 3 minutes of arc) misalignment of the mirrors can be tolerated. In other cases, the maximum tolerable misalignment may be less than one minute. The limiting angle decreases with decreasing generator power and with

medium as a function of the oscillation amplitude, with the pumping power kept constant: $G_n = f(U_{in})$. Experimental maximum and minimum laser power for nine filters whose transparencies lay within 0.74--0.01 is shown. The experimental laser negative conductance falls off as U_m increases, as is generally the rule in soft-excited oscillators. The Ne-He laser has a pronounced nonlinearity within the entire range (20 db of saturation power) of its output power. Orig. art. has 4 figures and 12 formulas.

TITLE: Measurement of the oscillator strength of the resonance line of calcium by the method of absorption in the atomic beam

PERIODICAL: Optika i spektroskopiya, v.14, no.3, 1953, 322-329

TEXT: The value of the oscillator strength of the resonance line Ca I 4227 Å was determined by measuring the contour of lines absorbed in an atomic beam. The concentration of atoms in the beam was determined by the rate of condensation of atoms on a plate, the weight of condensed Ca being determined by a spectro-analytical method. The construction of the calcium furnace is as described in an earlier article of the author (Opt. i spektr. v.6, 1959, 398). A discharge tube with a liquid nitrogen cooled hollow cathode and using helium at a pressure of 2 mm Hg as a working gas is used as a light source (current ~ 10 mA). The remainder of the apparatus consists of a Fabry-Perot etalon and a spectrograph with a photomultiplier as detector. The value for $f_{4227} = 1.6 \pm 0.1$

monochromator. The interferograms were scanned with an MF-2 micro photometer; the contour of the 6438 Å line shown in Fig 1 is the mean of the results obtained from four interferograms. Fig 1 shows that the contour of the red line of cadmium is strongly asymmetric, indicating unresolved fine structure, and its half-width is $(11.8 \pm 0.5) \times 10^{-3} \text{cm}^{-1}$. The latter value differs appreciably from $16.4 \times 10^{-3} \text{cm}^{-1}$, given by Minkowski and Bruck (Ref 4); the lower value reported above is due to the higher resolution of the apparatus used by the present authors. The empirical contour (continuous curve) is compared with a theoretical one in Fig 2. The theoretical (dashed) curve is the result of superposition of the isotopic components of the cadmium line, each of which has a natural half-width of $2.6 \times 10^{-3} \text{cm}^{-1}$; in derivation of the theoretical contour the apparatus and the Doppler half-widths were also allowed for. The theoretical contour agrees quite well with the empirical one and an even better coincidence can be obtained by displacing "the centres of gravity" of the odd isotopic components toward lower frequencies by $\sim 0.7 \times 10^{-3} \text{cm}^{-1}$. The large natural width of the components of the 6438 Å line places a theoretical

SOV/61-7-6-1/36

TITLE: Investigation of the Contour of the Cadmium Red Line, Using an Atomic Beam

PERIODICAL: Optika i spektroskopiya, 1959, Vol 7, No 6, pp 721-724 (USSR)

ABSTRACT: The red line of cadmium at 6438 Å is used as a wavelength standard and consequently knowledge of its true contour is of great importance. In 1935 Minkowski and Bruck (Ref 4) used an atomic beam source to find that the half-width of the 6438 Å line was $16.4 \times 10^{-3} \text{cm}^{-1}$. This value is much greater than the sum of the apparatus and Doppler half-widths, i.e. the red line of cadmium has complex structure and a considerable width. The present authors used an improved version of Minkowski and Bruck's method to study further the contour of the 6438 Å line of naturally occurring cadmium (a mixture of Cd106, Cd108, Cd110-114, Cd116 isotopes). An atomic beam, described earlier by Odintsov (Ref 6) was used to excite the line. A Fabry--Perot etalon was used; it had 15 cm separation between the plates and the reflectivity of the dielectric mirrors was 90%. The apparatus half-width of the etalon was $1.5 \times 10^{-3} \text{cm}^{-1}$ (Minkowski and Bruck's etalon had a separation between plates of 11 cm and an apparatus half-width of $3 \times 10^{-3} \text{cm}^{-1}$). An ISP-51 spectrograph with a UF-84 camera ($f = 800 \text{mm}$) served as a

respectively (these dimensions are taken at right-angles to the line of observation), h which is the distance between the two slits, \bar{v} which is the most probable velocity of atoms at the furnace temperature, c is the velocity of light and n_0 is the density of atoms in the furnace. Eq. 2 reduces to Minkowski and Bracke's formulae when $(a_1/2l) \rightarrow 0$. It is found that the value of a_1 does not affect greatly the line shape which is governed primarily by the values of s_1 , s_2 and h . The line becomes narrower at high values of s_1 ($a_1 \gg l$). There are 3 figures and 2 references, 1 of which is Soviet and 1 German.

SOV/51-6-5-2/34

TITLE: On the Shape of the Line Profile in an Atomic Beam (K voprosu o forme kontara linii v atomnom puzhke)

PERIODICAL: Optika i Spektroskopiya, 1959, Vol 8, Nr 5, pp 576-579 (USSR)

ABSTRACT: The spectral line profile produced by excitation (e.g. by electrons) of an atomic beam was discussed theoretically by Minkowski and Bruck (Ref 1). They obtained an expression for the intensity distribution in the line assuming that the exit slit of the furnace which produced the atomic beam was parallel to the line of observation and that the width of this slit was small. Odintsov showed recently (Ref 2) that in order to obtain intense atomic beams it is necessary to place the exit slit of the furnace at right-angles to the line of observation. The present paper follows up Odintsov's work by deriving an approximate equation (Eq 2) for the line shape produced in an excited atomic beam: it is assumed that $(a_1/2l)^2 \ll 1$, where a_1 is the dimension of the furnace slit in the direction at right-angles to the line of observation i.e. its length, and l is the distance from the furnace slit to the line of observation. Eq 2 involves s_1 and s_2 which are the dimensions of the furnace slit and the slit in a diaphragm outside the furnace

(USSR)

ABSTRACT: The author describes a high-intensity light source which uses an atomic beam excited by an electron beam. The source is shown schematically in Fig.3. Its main parts are a crucible 3 from which vaporised atoms proceed via a tube 5 and via collimating slits in rotatable drums 8 and 9 to a chamber where they meet the electron beam (shown dashed) produced by a gun 13. The crucible is heated to 800-900°C and the drums 8 and 9 are cooled with liquid nitrogen. The electron gun produces a beam of 4-5 A/cm² intensity. The various slits and distances are chosen to make the atomic beam as intense as practically possible (theory of the optimum dimensions of the collimating assembly is given). A vacuum of the order of 10⁻⁵-10⁻⁶ mm Hg is maintained in the apparatus. Observations are made at the

TITLE: Preparation of a solvent for the production of polyethylene

PERIODICAL: Khimiya i tekhnologiya topliv i masel, no.3, 1963, 19-22

TEXT: The solvent was prepared from commercial extraction grade benzene extracted from low-sulphur, paraffinic Groznyy crudes. The most suitable fraction of the benzene had the initial boiling points 75 to 95°C, benzene content 1.5 to 2.3 wt.%, sulphur content < 0.005 wt.%, naphthenic hydrocarbons 40 to 48 wt.%. The production costs of this solvent are lower than those for a similar solvent produced from catalytic reformates. The costs could be decreased further by employing fully instrumented and automatically controlled fractionating columns. The authors recommend that the centre for the production of solvents for the manufacture of copolymers should be situated in Groznyy because of its resources in raw materials. There are 1 figure and 4 tables.

pounds, and recovery of the solvent. In the proposed process of extraction use was made of I containing 5% water (addition of 5-15% water increases the solubility of aromatic compounds and decreases the solubility of paraffin hydrocarbons). As optimal temperatures of extraction of aromatic hydrocarbons have been recommended temperatures up to 120-140°; with a ratio of I, circulating in the system, to the processed raw material, of 5:1. The results obtained during the operation of the unit have confirmed the basic recommendations of Grom'II, submitted with the project data, and also the high efficacy of the process. -- A. Nagatkin.

Campaign to Limit Losses

92-58-5-14/30

As a result, the leakage of petroleum products was reduced. Special funnels were put under the sampling thiefs of stabilizers in order to collect products lost in sampling. A considerable amount of propane evaporates when it is loaded into steel cylinders. A suggestion was made which will reduce propane losses, and it is expected that it will produce good results. As a result of these measures and a number of other measures taken to limit petroleum product losses, the department has managed to limit such losses, so that they are now 3.4 percent lower than allowed by regulations.

TITLE: Campaign to Limit Losses (Bor'ba za sokrashcheniye poter')

PERIODICAL: Neftyanik, 1958, Nr 5, pp 16-17 (USSR)

ABSTRACT: Natural gasoline with narrow fractions and liquefied gaseous hydrocarbons are produced and stored under high pressure, and such products may escape and evaporate through even the smallest leak, which would be impassable for other products. Because of this fact, the department to which the author of the article belongs, has to overcome special difficulties in its campaign to limit petroleum product losses. To make the campaign against these losses successful, the personnel of the department had to attend lectures on the properties of gases and liquefied petroleum products and on special features of the refinery equipment which help to prevent evaporation of petroleum products. The personnel was also instructed to be particularly careful in carrying out certain operations and in handling certain gate valves, pumps, etc. A special course was organized for mechanics and operators who have to prepare and handle packers and stuffing boxes.

TITLE: Constant component of the Cardan error of gyroscopic devices during regular rolling

SOURCE: IVUZ. Priborostroyeniye, v. 9, no. 5, 1966, 105-109

TOPIC TAGS: gyro, gyroscope, error function

ABSTRACT: A simplified form of S. Rivkin's transformed formula for the Cardan error of a directional gyroscope unstabilized in the horizontal plane, assuming that the trim angles vary at the same frequency according to a harmonic progression and neglecting members containing their third orders, shows that during regular and symmetrical rolling the Cardan error possesses a constant component. An integral equation is given for this component, and formulas are deduced for its maximum value and for rolling phase angles $\phi = 0^\circ$ and $\phi = 90^\circ$. Numerical examples show that the constant component can reach significant values. During uniaxial rolling, the maximum error occurs at course angles of $\pm 45^\circ$ and $\pm 135^\circ$; during biaxial rolling, it depends on the relation between the roll amplitude and the phase angle, and is practically absent at identical amplitudes and $\phi = 90^\circ$. Gyroscopes on ships with a

TITLE: Improving linearity of gyroscopic tachometers and tachoaccelerometers

SOURCE: IVUZ. Priborostroyeniye, v. 6, no. 4, 1963, 71-77

TOPIC TAGS: tachometer, tachoaccelerometer, gyrotachometer

ABSTRACT: The problem is discussed of correcting nonlinearity of a gyro-tachometer that uses a standard transformer-type transducer (primary element) with a movable winding. The solution suggested is a further development of the author's method applicable to potentiometer-type transducers and published earlier ("Designing electrical elements of gyroscopic devices," Vysshaya shkola, 1962). Correction formulas investigated in the article cover both types of transformer, with distributed and with concentrated windings. Nonlinearity of the characteristic of the rotary transformer that measures the deflection angle
