TITLE: The Determination of Stray Losses in Synchronous Machines Operating Alone. (Opredeleniye dobovochnykh poter' v avtonomno rabotayushchikh sinkhronnykh mashinakh)

PERIODICAL: Vestnik Elektromyshlennosti, 1957, Vol.28, No.10, pp. 49 -52

ABSTRACT: Methods of determining stray losses in synchronous machines are not well developed. Stray losses are usually determined by Rüdenberg's method from the results of a short-circuit test. However, the current wave shapes are different on normal load and under short-circuit and so the losses determined on short circuit may be appreciably greater than on load. This effect is most marked in single-phase synchronous machines and also in asymmetrically-loaded three-phase machines.

This article suggests a method for the experimental determination of stray losses for any load condition on single and three-phase synchronous machines operating alone.

In order to determine the stray losses of a single-phase synchronous machine two operating conditions must be considered: short circuit and no-load. The recommended procedure is as follows: A single-phase generator with short-circuited field winding is driven up to its rated speed by an auxiliary motor

Card 1/3

The Determination of Stray Losses in Synchronous Machines
Operating Alone. 110-10-10/18

after which the armature winding is connected to an alternating current supply through a resistance equal to the total resistance of the load. After synchronisation the generator operates as a reactive single-phase synchronous motor. The auxiliary motor is disconnected while running and the no-load conditions are obtained for the synchronous machine. The voltage applied to the armature is such that the appropriate load current flows through the winding and the associated series resistance. Because of the presence of the external resistance all the current harmonics in the generator winding are practically the same as on normal load. This is confirmed by the oscillograms, Figs. 3 and 4. Therefore, the field harmonics for a single-phase synchronous motor operating, in this case, on no-load have the same influence on the generator windings as under actual load conditions. A slight difference in the saturation of the magnetic field may be neglected. A formula is given for the determination of the stray losses as the difference between the total losses and the sum of the mechanical iron and copper losses. Methods of determining these three types of loss are then described. Experimental data for stray losses card 2/3 in a single-phase synchronous generator operating under

The Determination of Stray Losses in Synchronous Machines Operating Alone. 110-10-10/18

reactive no-load conditions, on short-circuit are compared with calculated values in a table and the superiority of the new method of test is demonstrated.

Stray losses in three-phase machines can be determined by an analogous method provided that an appropriate impedance is connected to each phase of the machine. In this case there is no need for an auxiliary motor.

TITLE Controlled-Output D C Machines With Permanent-Magnet Field Systems

PERIODICAL: Vestnik elektropromyshlennosti, 1960, No 12 pp 42-48

TEXT Ordinary d c machines with permanent-magnet fields do not permit of direct control of field flux in the air gap. It is accordingly of practical importance to develop a simple and economic design of d c machine with permanent-magnet field in which the voltage can be controlled. A way of doing this which has been proposed by the present authors combines two methods of excitation: electromagnetic and permanent magnet. The armature commutator and brush gear are just the same as in an ordinary d c machine. Each field pole has two permanent magnet parts and between them is a magnetic shunt of magnetically soft steel. Under normal operating conditions the machine is excited jointly by the permanent magnet and the compensation winding which surrounds

Card 1/5

E194/E455

Controlled-Output D C Machines With Permanent-Magnet Field Systems

the pole as a whole. The permanent magnet flux passes through the air gap into the armature and is partially shunted, increasing the permanent-magnet leakage flux. Current is passed through the compensating winding in such a direction that its magnetic flux in the air gap coincides in direction with that due to the permanent magnets. Then the flux set up in the shunt by the compensation winding opposes the leakage flux of the permanent magnet which closes through the shunt. Any necessary increase in the working flux is developed by the compensating winding by displacing the leakage flux of the permanent magnet from the shunt into the air gap. In a conventionally excited machine the field winding should be capable of setting up an mmf that will cause all the permanent flux to pass round the magnetic circuit and will also compensate armature reaction and voltage drop in the armature circuit. By comparison, the machines with permanent magnets that are under consideration require much less mmf from the compensation winding. Most of the flux in the air gap is provided by the permanent magnets. If suitably designed, the machine with permanent magnet can have appreciable advantages over an ordinary machine. A number of

Controlled-Output D C Machines With Permanent-Magnet Field Systems

machines are compared in the article, all fulfilling the same requirements and having the same rated data. Results are given for the case of including a compensating winding (the magnetic fluxes of the permanent magnet and the compensating winding coincide in direction in the air gap). The following machines are compared with conventional excitation: with permanent magnets with orientated crystallization; with magnico permanent magnets, and with permanent magnets of high coercive force. Two frame sizes of d c motor are compared, firstly in respect of no-load characteristics. Very similar no-load characteristics can be obtained with and without permanent magnets, but with permanent magnets the field winding power is much reduced. Moreover, in motors with permanent magnets, the rated voltage may be exceeded by 25 to 30% which cannot be allowed with normal methods of excitation because of saturation of the magnetic circuit. The comparison shows that the alloy with orientated crystallization requires the least field power. The use of permanent magnets with high coercive force in four-pole machines has less to

Controlled-Output D C. Machines With Permanent-Magnet Field Systems

recommend it For self-excitation and starting, a d c. machine must have a relatively high residual flux and in this respect machines with partial permanent-magnet excitation are much superior to normal machines Motors of this kind can be started against rated load without special starting windings. It is shown that motors with permanent magnets made of alloys with orientated crystallization and magnico have a starting voltage which is 2.5 to 3.5 times less than in normal machines Alloys with high coercive force require a higher starting voltage which is 70 to 80% of the corresponding value for normal methods of excitation. D C. motors operated with speed controllers are often required to be of great reliability because of the high runaway speeds that could result from field failure Here motors with permanent magnets are particularly reliable because even if the compensation winding fails the excitation is sufficiently maintained. The field winding time-constants of machines with permanent-magnet excitation are much smaller than those of normal machines and accordingly, transient process time is greatly reduced In the

Card 4/5

E194/E455

Controlled-Output D C Machines With Permanent-Magnet Field Systems

ordinary way alloys of high coercivity cannot be magnetized in the assembled machines. However, in the machines described here this is possible because the compensating winding is wound directly on the permanent magnets and its full flux passes through the magnets along the axis of magnetization. The permanent magnet can accordingly be magnetized by passing through the coils a high value of direct current for a short time. The risk of de-magnetization by transient currents and short-circuit currents is considered and dismissed because the total flux of the magnet remains constant in such circumstances and the flux is redistributed between the air gap and the magnetic shunt. Commutation is practically the same in machines with permanent magnets and in normal machines. There are 7 figures 2 tables and 6 references: 5 Soviet and 1 English

Abstract: Review of the literature on the appearance and induction of "alcohol pain" in people with malignant granulomatosis, other malignancies, and other diseases. Although findings are not consistent, and cannot be used as a diagnostic test, the author believes that it could be utilized as a test for the progress of the treatment and aid in prediction of further possible foci of malignancy. TITLE: Modern leveling instruments and possibilities of faster surveying

SOURCE: Geodeticky a kartograficky obzor, no. 10, 1966, 270-274

TOPIC TAGS: surveying instrument, surveying equipment, geodetic survey

ABSTRACT: Surveyors leveling instruments are first classified in two groups: bubble levels and those with automatic adjustment to the line of sight. Four grades of accuracy are listed, as standardized in the Czechoslovak leveling instructions of 1950. Typical differences in design are described, including a fixed telescope attached to the bubble level and with an elevating screw, ocular observation facilitated by an optical micrometer in the form of a plane-parallel plate either in the telescope or before the objective. Improvements include focusing screws, vibration absorbers, and prismatic or reflector plummets. Levels produced by different manufacturers vary chiefly as to accuracy of adjustment, also as to weight and protection from effects of heat. Tables list such variations among levels produced by chief manufacturers in England, France, Hungary, Germany, Soviet Union, Switzerland, Italy, Czechoslovakia, Austria and Japan. Future improvements in geodetic equipment are briefly listed as:

Card 1/2

UDC: 528.541.2

ACC NR: AP7000592

a) use of lasers, with a computer to read their horizontal beam on an improved leveling rod and give the height directly; b) photographic registration of coded gradations on level rod (as with a coded theodolite); c) designing a leveling instrument with both forward and back fields of vision. A rotating telescope with two objectives, prismatic comparison of gradations on two rods, and an optical coincidence micrometer will be manufactured by the MOM firm in Budapest. Another means of speeding surveyors data is the use in computers of data transferred to punch tape. Orig. art. has: 8 tables.

"Hemolyzing Property of Organ-Extracts Containing the Viruses of In-
fectious Canine Hepatitis and Distemper"

Budapest, Acta Veterinaria, Vol 12, No 4, 1962; pp 409-415.

Abstract [English article; authors' English summary]: The organ extracts containing infectious canine hepatitis hemolyzed the erythrocytes of the guinea pig after incubation in a water bath at 40°C for an hour. The hemolytic titer of the liver extracts ranged between 1:8 and 1:256 that of the lymph node and spleen extracts between 1:4 and 1:64, whereas the lung extracts hemolyzed only up to 1:2 dilution. The hemolysis was preceded by a release of K⁺ from the erythrocytes. The hemolytic titer depends on the species of animal giving the erythrocytes, on the concentration of the erythrocytes and on the temperature. The hemolyzing agent cannot be destroyed either by formalin in a concentration of 0.4% or by heating at 56°C for 30 minutes. Boiling for 10 minutes destroyed the hemolyzing activity. The hemolyzing material was partly

"The Hemolytic Effect of the Pancreas Extract of Normal and Swine
Fever Infected Pigs."

Budapest, Magyar Allatorvosek Lapja, Vol 5, No 18, May 63, pp 210-211.

Abstract: [Authors' English summary modified] The hemolytic activity
of pancreas extracts of pigs decreased after infection with virulent
swine fever virus or inoculation with lapinized virus. The pancreas
extract showed a hemolytic activity in dilutions less than 1/512 in
87 per cent of the infected pigs, but 78 per cent of normal pig ext-
tracts produced hemolysis even in a higher dilution. The demonstration
of the decrease of hemolytic activity serves no diagnostic purpose
since it varies greatly with the age of the animal and because it can
also be demonstrated using pancreas extracts of pigs infected with
Aujeszky's disease or swine erysipelas. 4 Western, 3 Eastern European

TITLE: X-ray investigation of alloys of some metals with sulfur

PERIODICAL: Referativnyy zhurnal. Metallurgiya, no. 1, 1962, 4, abstract 1122
(Uch zap. Khar'kovsk. un-t, 110, Tr. Khim. fak. 1 N.-1. in-ta
khimii KhGU, 17, 109 - 120)

TEXT: Alloys of Ag, Cu, Cd, Zn, In, Pb, Sn, Ge, Bi and Sb with S prepared by the method of Academician S. A. Vekshinsky were investigated. As initial materials were taken Ag (99.92%), Sn (99.94%), Cu (99.97%), Pb (99.99%), Bi, Zn and Cd of (ch.d.a.) grade, Sb (99.2%), In (99.98%), Ge (99.9%) and stick sulfur after a 4-fold vacuum distillation. The investigation was carried out by X-ray method and with radioactive isotopes (S^{35}). A relatively stable vitreous state was established in Cu-S (65 - 80% S), Ag-S (70 - 90% S), Sn-S (75 - 85% S), Pb-S (75 - 85% S), Bi-S (70 - 80% S), Zn-S (45 - 70% S), Cd-S (40 - 70% S), In-S (25 - 80% S), Ge-S (15 - 60% S), Sb-S (5 - 90% S) alloys. It is pointed out that the range of S concentration, within which the vitreous state is stable, extends with the increased ability of metal to stay in amorphous state. Diagrams of meta-

TITLE: A general property of two-dimensional modulated servosystem 9,44

SOURCE: Avtomatika i telemekhanika, no. 1, 1966, 74-86

TOPIC TAGS: servosystem, automatic control system

ABSTRACT: The author investigates a two-dimensional servosystem consisting of an a-c circuit and a linear two-channel section. The derivation of the general transfer function of linear two-channel systems is given. It is demonstrated that in the case of arbitrary demodulation functions and general transfer functions the Q-factor remains bounded even if the amplifications of the individual stages tend to infinity. Since the d-c component at the output of the phase detector is a linear combination of the amplitudes of error harmonics, an infinite increase in the system's amplification reduces only the amplitude combination to zero and not each of the components separately. This is equivalent to the effect of an additional negative feedback. Author thanks E. N. Petrov for his interest and Card 1/2

TITLE: On propagation of a free axial symmetrical turbulent jet of finite dimensions

PERIODICAL: Referativnyy zhurnal Mekhanika, no. 8, 1961, 33, abstract 8B2:7 ("Izv. AN KazSSR. Ser. energ", 1960, no. 2 (18), 84-92, Kazakh summary)

TEXT: The author describes the results of a theoretical and experimental investigation of a slightly heated jet of finite dimensions in a stationary surrounding medium at non-uniform distribution of velocities (at outlet from the nozzle). In theoretical analysis the hypothesis was made that equations of boundary layer for heat and momentum transfer can be reduced to linear differential equations of the type of heat conductivity equation with corresponding boundary and initial conditions. Three cases of initial velocity profiles at the outlet from the nozzle are considered: 1) uniform profile, 2) developed turbulent profile, and 3) profile corresponding to outflow from two concentric axial symmetrical nozzles at different ratios of dimensions of the latter. The solu-

tions of the equations are obtained in the form of iterated integrals of the initial stream distribution, density of momentum or heat content, given by the initial conditions, and Bessel functions with arguments depending on nozzle dimensions. These integrals were calculated approximately with the aid of a hydrodynamical integrator. In experiments, fields of density of momentum stream in transverse cross sections of the jet were obtained. Calculated and experimental data were compared and found to agree satisfactorily. There are 9 references.

AUTHORS: Vulis, L. A., Palatnik, I. B.

TITLE: Mechanism of turbulent mixing in gas flows

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, v 4, no 9, 1961, 5-11

TEXT: The experimental arrangement shown in Fig. 1 was used to study the turbulent mixing of a gas jet with a gas flow of different temperature. The limits within which the parameters of gas jet and gas flow were varied, are listed in Table 1. In their experiments, the authors determined the velocity head and the temperature distribution along the axis and over the cross section. The velocity head was measured with a Pitot tube 2 mm in diameter, and the temperature was determined by means of a platinum-platinum rhodium thermocouple. The turbulence of the gas jet and of the gas flow at the exit section of the nozzle was measured by means of a STAM-3A (ETAM-3A) electrothermoanemometer. The flow velocities were computed from measurements of q_r and ΔT . As characteristics for the intensity of turbulent mixing at a given point of the flow, the following relations were used $\epsilon = 1 - (u^2)_{\text{min}} / (u^2)$ and

Card 1/6

Mechanism of turbulent mixing

57212
S/170/01/004/001/0111
3104/3125

$\epsilon_T = \frac{T_m - T_n}{T_o - T_n}$, where the subscript m refers to the axis of the jet. These characteristics tend toward zero in the absence of mixing and toward unity with complete mixing. The authors determined the function $\epsilon_T = f(m)$, where $(m^2 = (\overline{u^2})_m)$; it may be seen from this function that at any given distance from the mouth of the nozzle, the quantity ϵ_T and consequently, the conditions for a minimum mixing of the jet with the flow practically coincide at $m = 1$. In this case, jet and flow have the same velocity. The decisive role played by the density of the pulse flow in turbulent mixing may be seen from the function $\epsilon_T = f(m)$. Measurements were then obtained at one and the same point on the axis of the jet ($x/d_o = 5$; x is the distance from the mouthpiece of the nozzle, and d_o is its diameter) at different temperatures. The relative disposition of the curves $\epsilon_T = f(m)$ indicates that the damping rate of the jet varies with increasing temperature. The decrease of the quantity $\Delta T_m / \Delta T_o$ and also of u_m / u_o with $\omega = T_o / T_n > 1$ is greater than with $\omega \approx 1$. On the basis of the "similarity of $\overline{u^2}$ " it is shown that a universal dependence of $(\overline{u^2})_m / (\overline{u^2})_o$

Card 4/6

Mechanism of turbulence mixing ...

on x/d_0 on the axis of the jet is confirmed by the results of an experiment. Moreover, it was found that the quantity (ρ_0^2/ρ_0) drops the more, the higher is the temperature of the gas jet. The mixing process accelerates slowly and continuously with ω . With slight heating the level of pressure pulses rose from 1-2% at $\omega = 1$ to 10-12% at $\omega = 3$; with intense heating, values of 3-4 and 12-15% were obtained at the analogous values of ω . G. N. Abramovich is mentioned. There are 4 figures, 1 table, and 7 Soviet references.

TITLE: Diffusion of free turbulent jets flowing from a rectangular nozzle

SOURCE: Ref. zh. Mekhanika, Abs. GB385

REF SOURCE: Sb. Prob. teploenerg. i prikl. teplofiz. Vyp. 1. Alma-Ata, AN KazSSR, 1964, 18-28

TOPIC TAGS: nozzle flow, annular nozzle, turbulent jet, flow velocity, jet flow

TRANSLATION: The problem of propagation in the motionless atmosphere of a turbulent jet flowing from a rectangular nozzle was examined. Noting the fact that the initial system of equations was not closed and that it contained unknown correlations of velocities and gave only two equations for determining three component velocities, the authors attempted to find the field of the longitudinal component of the velocity, leaving the other two components undetermined. The method used

Card 1/2

L 17782-66

ARTICLE NUMBER: AR5020403

was that of the equivalent problem of the thermal conductivity theory, i.e., the conversion of the system of coordinates was introduced, reducing the equation for determining the longitudinal component of the impulse to the equation of thermal conductivity, in which the functional relation describing this conversion had to be determined by the test. An experimental study was made also of the expansion of an immersed rectangular jet. During these tests a determination was made of the distribution of the longitudinal component of the impulse in the various lateral profiles of air jets flowing into the motionless air from nozzles with discharge cross sections of 20 x 20, 15 x 30, and 10 x 30 mm and a 39 m/sec velocity. A comparison of the experimental and calculated distributions of the impulse along the axis of the jet made it possible to determine the type of relationship, describing the conversion of the coordinates, for each of the cases studied and also for nozzles with lateral ratios of 1:5 and 1:20; the experiments on the latter were conducted by V.A. Turkus. With the help of these empirical functions and the solution of the thermal conductivity equation of the profile of the longitudinal impulse component in the various lateral profiles of the jet, comparisons were made with the corresponding experimental data. An estimate was given of the distance from the nozzle at which the jet flowing from the rectangular nozzle acquired an axial symmetry. References 13. O.V. Yakovlevskiy.

TITLE: The propagation of free turbulent currents originating from rectangularly-shaped nozzles.

SOURCE: Alma-Ata. Kazakhskiy nauchno-issledovatel'skiy institut energetiki. Problemy teploenergetiki i prikladnoy teplofiziki, no. 1, 1964. Prikladnaya teplofizika, 18-28

TOPIC TAGS: free turbulent current, rectangular nozzle jet, rectangular jet current density, rectangular jet momentum density, radial jet velocity, turbulent current propagation, aerodynamics

ABSTRACT: One of the problems of applied gas dynamics of jet flow is the propagation of currents originating from rectangularly shaped openings. However, existing theoretical discussions (see, e.g., I. B. Palatnik, Izvestiya AN KazSSR, seriya energeticheskaya, 1960, no. 2 (18); Sh. A. Yerzhin, L. P. Yarin, Izvestiya AN KazSSR, seriya energeticheskaya, 1962, no. 1 (21)) could not be brought to a successful conclusion since the investigations (see, e.g., V. A. Turkus, Otopleniye i ventilyatsiya, 1933, no. 5; I. A. Yavorakiy, Izvestiya Sibirskogo otdeleniya AN SSSR, 1958, no. 2) did not supply enough information about the initial velocity distributions at the exit of the nozzle.

Card 1/2

L 52269-65

ACCESSION NR: AT5011661

Consequently, the present authors carried out detailed experimental studies of the flow fields of free turbulent currents originating from rectangularly-shaped nozzles for various length-to-width ratios. Experimental data concerning the current and momentum densities at various cross sections of the jet agree with the corresponding theoretical predictions (using the equivalent heat-conductivity method) within the accuracy needed for practical applications. TOPIC TAGS: heat transfer, jet, combustion

ABSTRACT: The aerodynamics and heat transfer in nonisothermal cocurrent jets are important for the intensification of combustion processes. A comprehensive program to study this problem was conducted at the Kazakh Scientific Power Engineering Institute in 1962-1963. The experiments were carried out in a wind tunnel with a test section 0.6 m in diameter. The jet was preheated by passage through a combustion chamber in which butane-propane was burned. The jet was then injected into the test section through a nozzle 0.05 m in diameter. The velocity of the cocurrent air stream in the test section was varied between 10 and 20 m/sec to obtain ratios of the

Card 1/2

L 39537-66

ACC NR: AT6006926

cocurrent stream to jet velocity of 0—0.482. Dynamic pressure, static pressure, and temperature profiles were measured by means of a special probe. The data were correlated in terms of excess momentum and heat capacity. Comparison with theoretically calculated relationships showed that similar problems in the theory of heat conduction can be used for calculating jets of finite dimensions flowing in cocurrent streams. TOPIC TAGS: turbulent jet, mass transfer, fluid flow

ABSTRACT: For a three-dimensional flow, the field of the longitudinal component of the density of the momentum flux can be described by an equation of the form:

$$\frac{\partial \rho u^2}{\partial z} = \frac{\partial^2 \rho u^2}{\partial z^2} + \frac{\partial^2 \rho u^2}{\partial y^2}, \quad (1)$$

where $\tau = \tau(x)$ is the subject to experimental determination as a function of the longitudinal coordinate x , and x and y are the transverse coordinates. For the case under consideration, this equation must be solved with the following boundary and initial conditions:

Card 1/3

I 24260-66

ACC NR: AT6006928

$$\left. \begin{aligned}
 & \tau = 0, \quad |y| \leq a \\
 & x = 0, \quad |z| \leq b \\
 & y = 0 \\
 & z = 0
 \end{aligned} \right\} \rho u^2 = \rho u_0^2 = \text{const}$$

$$\left. \begin{aligned}
 & \frac{\partial \rho u^2}{\partial y} = 0; \quad \frac{\partial \rho u^2}{\partial z} = 0 \\
 & y \rightarrow \infty, \quad \frac{\partial \rho u^2}{\partial y} \rightarrow 0; \quad \rho u^2 \rightarrow 0 \\
 & z \rightarrow \infty, \quad \frac{\partial \rho u^2}{\partial z} \rightarrow 0; \quad \rho u^2 \rightarrow 0
 \end{aligned} \right\} \text{Eq. (2)}$$

The solution of Eq. (1) with boundary and initial conditions (2), obtained by summation with respect to the initial conditions, has the following form:

$$\frac{\rho u^2}{\rho u_0^2} = \frac{1}{4\pi\tau} \int_{-a}^a \int_{-b}^b e^{-\frac{(y-\alpha)^2 + (z-\beta)^2}{4\tau}} d\alpha d\beta \quad (3)$$

in which integration with respect to α and β is performed with respect to the area of the initial cross section of the nozzle. Experimental results lead to the conclusion that application of the method of the equivalent problem of the theory of heat conductivity gives fully satisfactory results and can be recommended for approximate calculation

ABSTRACT: Experimental data on the distribution of the pulsed flow density and enthalpy in the flow field of a submerged, slightly heated jet, issuing from a cross-shaped nozzle is compared with a solution obtained using the method of an equivalent problem of the thermal conductivity theory. It is demonstrated that this method can be used to calculate the flow fields under conditions where other calculation methods can not be applied. Orig. art. has: 5 figures and 8 formulas.

TITLE: Selection of optimum characteristics of ²gas turbine combustion chamber flame holder

SOURCE: Alma-Ata. Kazakhskiy nauchno-issledovatel'skiy institut energetiki. Problemy teploenergetiki i prikladnoy teplofiziki, no. 3, 1966, 94-98

TOPIC TAGS: gas turbine, combustion chamber, combustion chamber flame holder, ~~gas turbine~~, flame holder

ABSTRACT: Experimental results are presented on the selection of certain parameters of a gas turbine combustion chamber flame holder. The experiments were conducted to study the problem of hydraulic drag, (particularly pressure drop across the perforations) and nonuniform mixing under variable operating conditions. To determine the effect of a reduction in pressure drop on the quality air-fuel mixing, tests were conducted with \bar{S} parameter variations in the range $0.5 \leq \bar{S} \leq 0.8$ (where \bar{S} is the ratio of the total area of perforations to the flame holder cross section). The obtained results show that the pressure

2

drop across the perforations can be reduced if the relative pitch between the perforations is not smaller than 2.6 (where the relative pitch is defined as the ratio of the distance between the center of a perforation and its diameter). It was also found that at the same pressure drop, round perforations are more effective than the rectangular, i.e. they produce better air-fuel mixing. Orig. art. has: 5 figures and 1 formula. [AS]

NOTE: This book is intended for scientists and researchers in
 the field of spectroscopy, as well as for technical personnel
 using spectrum analysis in various industries.

CONTENTS: This volume contains 177 scientific and technical studies
 of atomic spectroscopy presented at the 10th All-Union Confer-
 ence on Spectroscopy in 1956. The studies were carried out by
 members of scientific and technical institutes and include
 articles covering many phases of spectroscopy: spectra of rare earths,
 ultraviolet radiation, physicochemical methods for controlling
 uranium production, absorption theory, spectrum analysis of ores
 and spectroscopy, abnormal dispersion in metal vapors,
 spectra and the combustion theory, quantitative spectroscopy
 and minerals, photographic methods for quantitative spectroscopy
 analysis of metals and alloys, spectral determination of the
 hydrogen content of metals by means of isotopes, analysis of
 alloys of spectral lines, spark spectrographic analysis
 statistical study of variation in the paramagnetic spectra
 curves, determination of traces of metals, spectrum analysis in
 metallurgy, thermochemistry in metallurgy, and principles and
 practice of spectrochemical analysis.

"Phase Transformations During Spark Machining of Metals and the Experiment of Establishing a Criterion for Interactions Observed," L. A. Palatnik, Kharkov State U in A. M. Gor'kiy

DAN SSSR, Vol 89, No 3, pp 455-458

Discusses results of X-ray analysis of crystal phases detected in surface layer of metals after spark treatment with various electrodes, presenting data on about 100 combinations of unlike

(1)

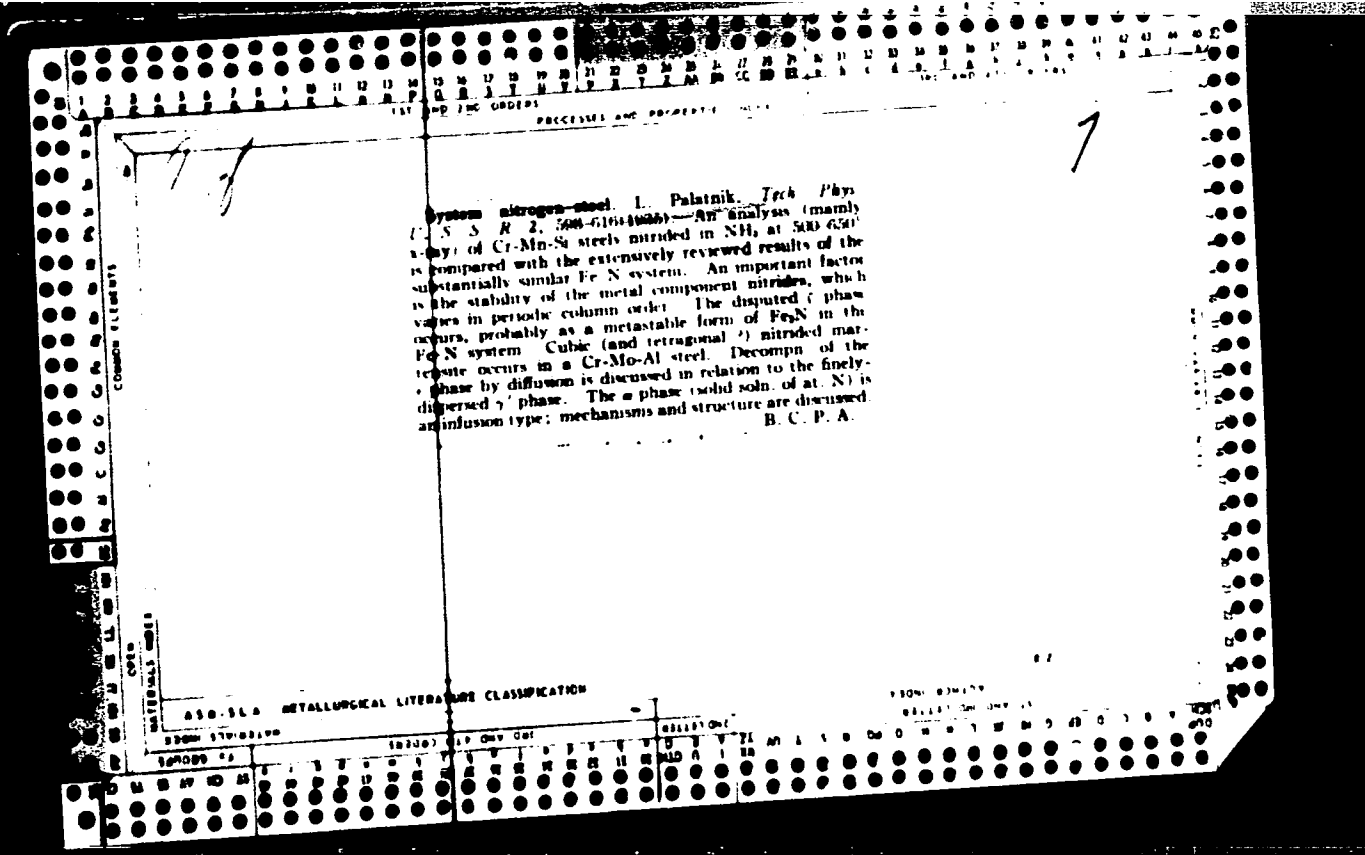

272131

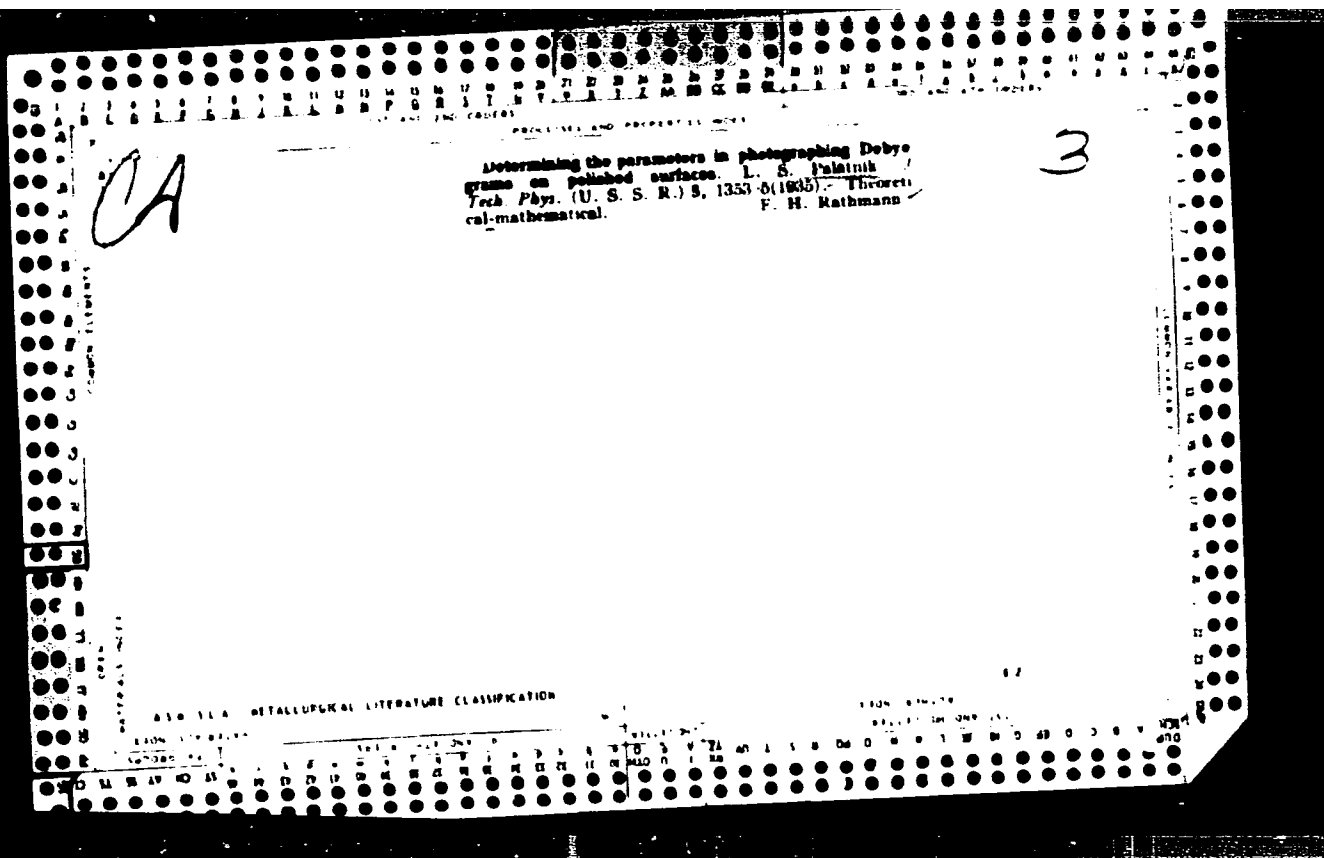

electrodes. Distinguishes following forms of interaction between substances of electrodes: formation of coatings on cathode out of anode material; formation of alloys (mixts, solid solns, or intermetallic compds) in surface layer of cathode as result of mutual diffusion of anode and cathode elements; transfer of substance from cathode on anode with formation of coatings or alloys. Suggests approximate criterion of transfer and interaction. It is expressed by ratio between periods corresponding to initial stages in origination of centers of melting and intensive evaporation in "working volumes" of electrodes. Develops formula and gives graphical

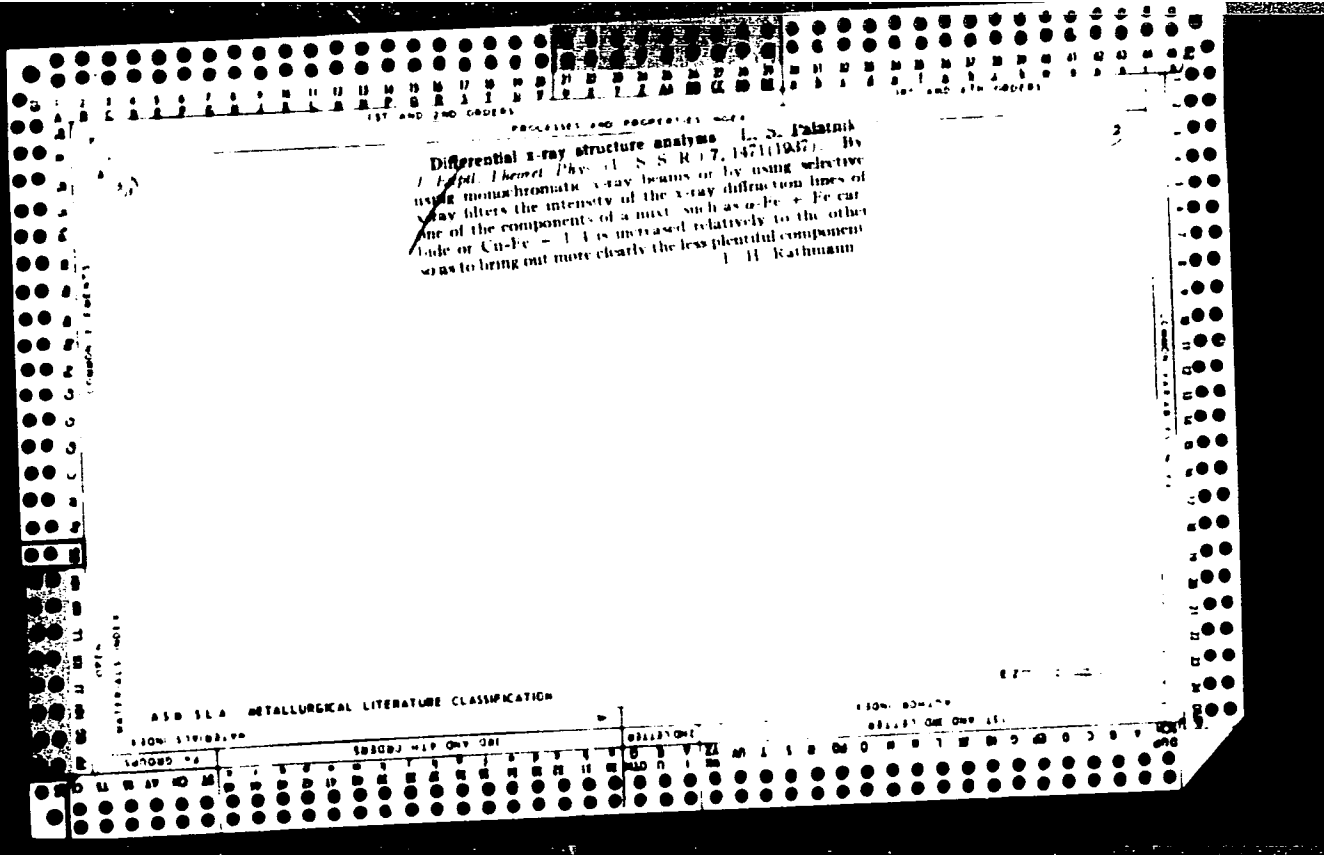

(2)

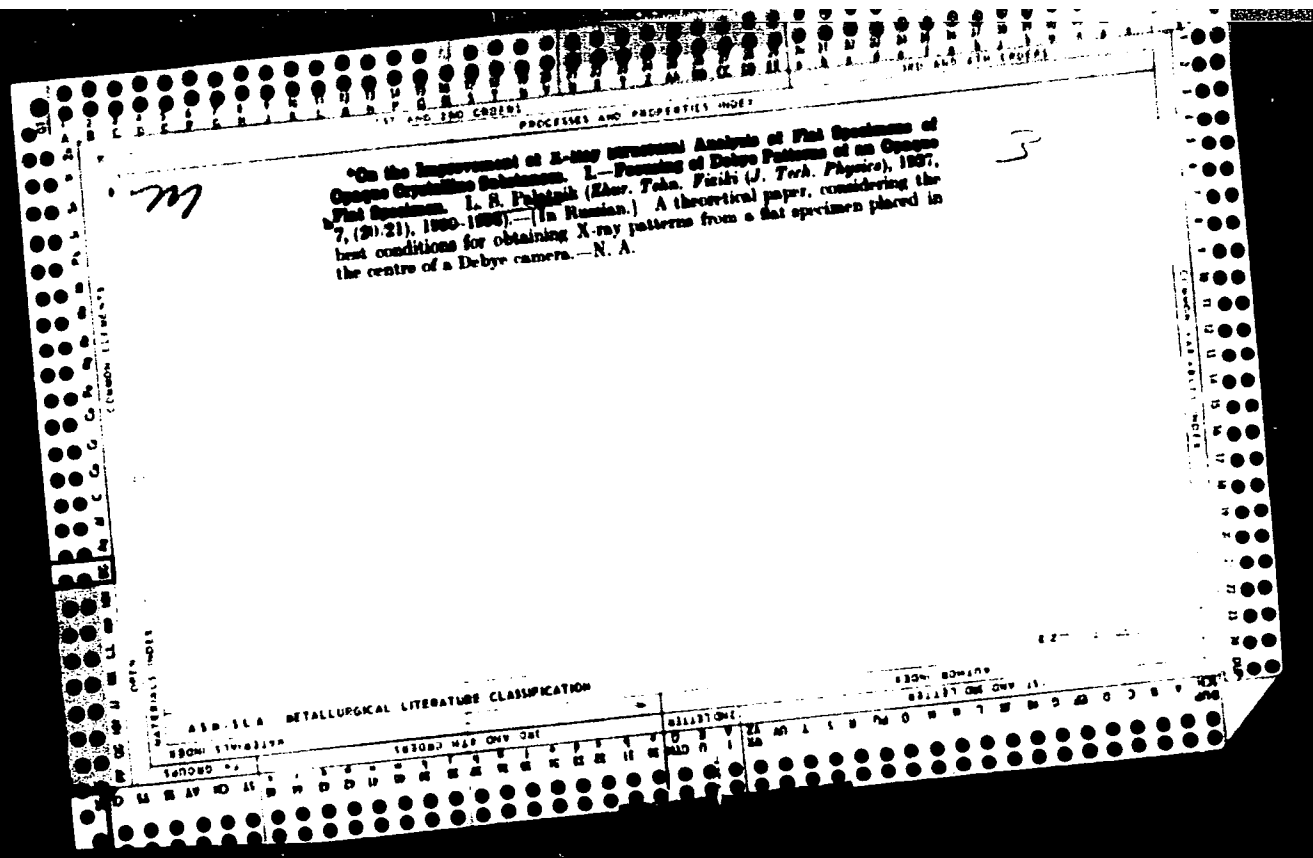

272131

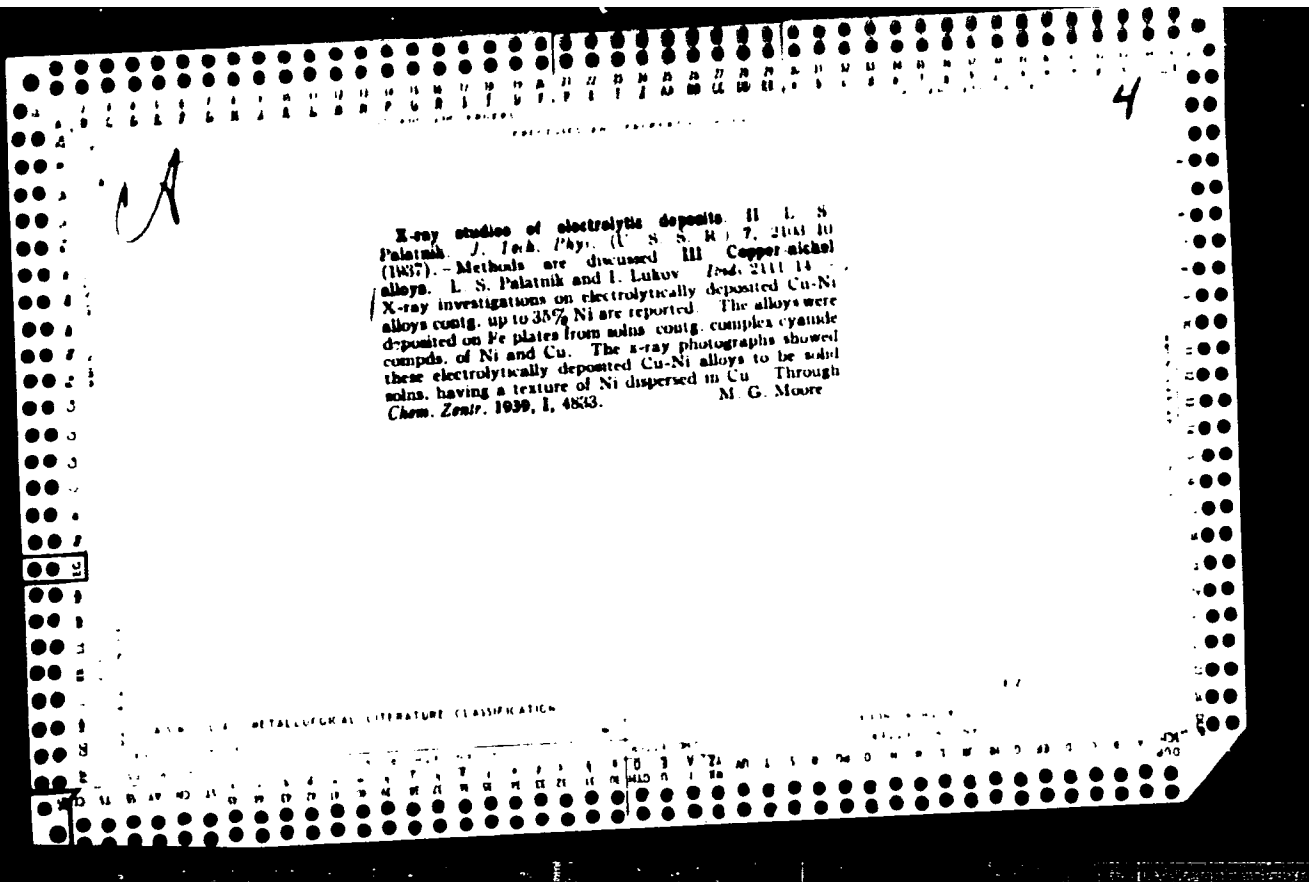

representation of criterion. States that criterion satisfactorily explains results of industrial experience and shows additional ways to increase effectiveness of spark machining of metals and their anti-corrosive protection, and also ways to decrease erosion of elec contacts and to improve accuracy of spectrum analysis of alloys. Submitted by Acad G. S. Landsberg 29 Jan 53.

Magnetic-electric conducting alloys. I. S. Palatnik. *Elektricheskoe* 1960, No. 2, 64.—The two-phase alloys Ag-Fe and Ag-Fe-Ni are suggested as magnetic-electroconductors. The wt. concns. of the components A (Ag) and B (Fe or Fe-Ni) should be selected in accordance with the desired characteristics of the alloys. The alloys are prepd. by any of the following methods: (1) sintering of the powders of A and B when the cond. is to be in 3 dimensions, (2) electrodeposition of successive layers of A and B (with further heat-treatment, e. g., for Ag-Fe-Ni) when cond. is to be in 2 dimensions, and (3) compression of packets of fine wire when cond. is to be in 1 dimension. For the last 2 cases the alloy Cu-Fe is recommended if it is not subjected to high temps. B. Z. Kamich

Composition and Structure of Alloys for Electrical Contacts. I. S. Palatnik.
(Elektricheskoye [Electricity], 1940, (4), 29-32; Modern Tech. Elect. Co. Tech. News Bull., 1940, (723)) [In Russian.] P refers to the currents passing through the contacts of electrical apparatus when closed (20 000 amp) or when breaking (1000 amp. or more), and to the resultant destructive effect on the contacts. Under such conditions, silver, and particularly copper, rapidly deteriorate due to welding, oxidation, &c. Monometallic contacts are therefore often replaced by those made of special alloys. The requirements of such alloys and their selection are discussed.
