PANČEĽ, M.

13. Investigations on carotenoid pigments. I. Pigments of the red tomato-paprika (In German) — J. Chotík, L. Györgyi, E. Nagy, M. Pánčel.
Acta Chimica Academiae Scientiarum Hungaricae, Vol. 6, 1953, No. 1-2, pp. 133-171; 2 figs., 3 tabs.)

The carotenoid pigments of the green unripe fruit, the red ripe fruit and green leaves of the red paprika variety *Capsicum annuum var. lycopersiciforme rubrum* were investigated by qualitative and quantitative chromatographic methods. Two stages may be distinguished in the development of the fruit. In the first stage due to its chlorophyll content the fruit is green, in the second it turns red simultaneously with the gradual disappearance of the chlorophyll. Alpha- and beta-carotene were found in the fruit and leaves containing chlorophyll; however alpha-carotene was found only in the leaves and none in the fruit. It was established that the unripe fruit contains xanthophyll but no zeaxanthin whereas the ripe fruit contains zeaxanthin but no xanthophyll. During ripening the chlorophyll disappears and the quantity of carotenoids increases very rapidly. These experiments showed that the physiological role of the carotenoids in the fruit and leaves containing chlorophyll is the transportation of oxygen. In the performance of this function they undergo changes and are transformed as stated above.

(3)

Carotenoid pigments I The pigments of red tomato-shaped paprikas (*Capsicum annuum* var. *indianum*) have been studied by K. Goto, T. Ueda, M. Matsunaga, and S. Yamada (J. Am. Oil Chem. Soc., 1971, 48, 1001).
The pigments isolated from the paprika were fractionated into three groups: A, B, and C. The pigments in group A have been isolated and identified. They were hydrolysed and separated into three main carotenoid constituents. These were identified as β -carotene, α -carotene, and light petroleum and benzene solubles, respectively, in 40%, 30%, and 30% yields, respectively. Pigments were identified by their absorption spectra. Carotenoids definitely identified in A are β -carotene (I), β -carotene- γ -epoxide (VIII) (trace), mutatochrome (III), $\alpha\beta$ -carotenes B and U (III), violaxanthin (IV), xanthophyll (VII), lutein, foliochrome, and antheraxanthin (V) (trace); in B I, aurochrome, II, cryptoxanthin, cryptocapsine, III, capsorubin, capsanthin, IV, V, xanthophyll-epoxide, zeaxanthin (VI), and the $\alpha\beta$ isomers of some of the above; in C the same as A, with α -carotene (IX). It is concluded that the physiological role of carotenoids is the transport of oxygen. The main route is VI \rightarrow V \rightarrow VII. The secondary route I \rightarrow VIII \rightarrow IX is only effective at high rates of oxygen metabolism. The changes during roasting are discussed. A. B. Densham.

TITLE: The possibility of formation of triatomic molecules in the solar atmosphere

SOURCE: Astronomicheskiy zhurnal, v. 44, no. 1, 1967, 91-93

TOPIC TAGS: astrophysics, solar spectrum, spectroscopy, molecule, photosphere, Diatomic, THERMODYNAMIC EQUILIBRIUM, SOLAR ATMOSPHERE

ABSTRACT: Assuming local thermodynamic equilibrium for the Utrecht reference model, the concentration ratios $n(\text{CH})/n(\text{CH}_2)$, $n(\text{NH})/n(\text{NH}_2)$, $n(\text{C}_2\text{H})/n(\text{C}_2)$, $n(\text{OH})/n(\text{H}_2\text{O})$, $n(\text{CN})/n(\text{HCN})$, and $n(\text{CO})/n(\text{HCO})$ are calculated as functions of the optical depth in the photosphere. The calculations show that triatomic molecules form an insignificant part of diatomic molecules. Apparently, for small deviations from the condition of the local thermodynamic equilibrium the disappearance of the diatomic molecules, AB and A_2 owing to the formation of the triatomic molecules ABH , A_2H and AH_2 can be neglected. ORG: State Astronomical Institute im. P. K. Shternberg [Gos. astronomicheskiy in-t]

TITLE: Determination of rotational temperatures from the lines of first overtones
of carbon monoxide in the solar spectra

SOURCE: Astronomicheskiy zhurnal, v. 43, no. 4, 1966, 708-717

TOPIC TAGS: rotational temperature, solar spectrum, sun, vibrational band, rotational
band, photosphere, chromosphere, carbon monoxide, SOLAR PHOTOSPHERE

ABSTRACT: The rotational temperatures of the vibrational, rotational CO molecular
bands 0-2, 1-3, 2-4, 3-5, 4-6 in the solar photosphere are determined. The
observational data were obtained with the ATB-1 telescope (dispersion of 1.6 Å/mm) of
the Sternberg Astronomical Institute. Semitheoretical arguments, based on the
quantummechanical considerations of Herman and Wallis, are given for the application
of the I and I + 1 intensity factors for the P and R branches of the first overtone
lines of CO. Within the measurement precision the rotational temperatures of all the
bands studied are practically the same (with the exception of the 4-6 band, which is
located in the region of strong atmospheric water-vapor bands). The mean rotational
temperature is 4850 ± 100 K (mean quadratic error). The value of the error leads to
doubts of the presence of thermal nonuniformities as indicated by Newkirk, who used

UDC: 523.774

Card 1/2

ACC NR: AP6028785

Minnaert's model and studied the center-to-limb behavior of the equivalent widths of certain CO lines. However, this photospheric model is not of sufficient accuracy for the transition region. The error of determination may be an additional factor responsible for the detection of nonuniformities. The almost identical rotational temperatures found for different vibrational-rotational bands of the first overtone of CO are evidently a result of the thin layer from which this overtone originates. Collisions of molecules with hydrogen atoms and electrons can also result in a Boltzmann distribution corresponding to the general kinetic temperature of constituent particles of the transition region between the solar chromosphere and photosphere.

The neurovascular reaction, as evaluated by means of the histamine test, is increased in more than 50% of all pregnant women. The reactions can be normalized in such cases by treatment with vit. C and P. Determination of vit. C in the blood of pregnant women nearing term showed considerable differences between treated and non-treated women. In the treated women, the vit. C concentration showed an increase of 110%; comparison of cord blood, however, showed only the insignificant difference of 2.3% between treated and untreated mothers.

trees as a Biochemical Index to Determine
the Phenophase More Exactly.

ORIG. PUBL. : Gradina, via si livada, 1958, 7, No.3, 33-38

ABSTRACT : It has been determined by the Institute of
Agronomic Research (Rumania) in 1953-1957
that the maximum chlorophyll content in the
leaves corresponds to the period of inten-
sive vital activity of the tree (fruit matu-
rity, intensive shoot growth, accumulation
of stored substances). The first increase
in chlorophyll content in the leaves corre-
sponds to the period of intensive biochemical
processes occurring in the fruit: sugar

648. CONTRIBUTIONS TO THE STUDY OF ANTITYPHOID AND ANTICOLI BACTERIOPHAGES SPREADING IN SURFACE WATERS. THEIR IMPORTANCE IN APPRECIATING THE SANITARY VALUE OF WATER.
Contribuții la studiul răspândirii bacteriofagilor antitifici și anticolici în apele de suprafață. Semnificația lor în aprecierea stării sanitare a unei ape. Sturdza S., Pantelescu M., Aronovici A. and Giurgea M. Inst. de Ig. R. P. R., Sect. de Ig. Comunală, București.

IGIENA (București) 1956, 1/2 (6-22) Graphs 24

The present paper is meant to show the importance of enteric bacteriophages as a general pollution indicator of surface waters, as an epidemiological indicator as well as regards their intervention in the self-purification processes. These studies proved that the frequency and the ratio between antityphoid-coli bacteriophages is in connection with the bordering settlements and increase with the degree of contamination. The frequency of typhocoli bacteriophages is also influenced by rainfall and by the hygienic standard of the respective territory and its inhabitants. There is a relation between the resistance frequency of the typhoid Vi bacteriophages and the local epidemiological state: the typhoid and coli bacteriophages do not participate in the self-purification process of surface waters; on the contrary in the self-purification zones they are disintegrated. An evident parallelism is noticed between the data concerning pollution presented by the bacteriophages and other bacteriological and chemical indicators used.

PROTECTING AREAS WHICH ARE NOT TO BE MITRIDED (BY COPPER AND TIN PLATING)
A.I. Pandratov (Vestn. Mashinostroeniya, 1958, 28, (2/3), 70-71; C.Abs.
1947, 41, 79) (In Russian) Areas not to be mitrided are protected success-
fully by covering them with a layer of copper followed by a layer of tin.
Both layers are covalently applied electrolytically. the copper layer, not
less than 15 μ thick, is deposited from a bath containing copper 15-22g.,
free in cyanide 10-15 g., carbonates 30-60 g., and water 1L. The temp.
of the bath is 35°-40°C., and the catodic c.d. 0.6 amp./dm.2 to the tin layer,
up to 3 μ hydroxide 4-10 g., sodium acetate 5-30g., and at 1L. The
bath temp. is 65°-70°C., and the cathodic c.d. 1 amp./dm.2
