AUTHOR: Pavlov, K. B. (Moscow)

TITLE: On the Prandtl-Mayer Type of Motion

PRIKladnaya matematika i mekhanika, 1960, Vol 24, Nr 1,  
pp 165-166 (USSR)

ABSTRACT:  
In a Prandtl-Mayer type of motion about a body, all flow quantities are functions of the cylindrical coordinate angle (only the z-axis is directed along the edge of the surface acute angle). This is not true, for example, when a bow shock occurs in front of the body. The author sets up linearized equations characterizing the density and components of velocity  $v_r$  and  $v_z$  for the more general case, when the initial values of the quantities are almost constant, by means of a perturbation about the above automodel solution. By writing the system of equations in matrix form, and by using the characteristic values of one of the co-

TITLE: On the Stability of the Flow of a Viscous Conducting liquid Between Parallel Planes in a Vertical Magnetic Field  $\eta$

PERIODICAL: Prikladnaya matematika i mehanika, 1960, Vol. 24, No. 4,  
pp. 723-725

TEXT: The parabolic distribution of the velocities in a flow between two parallel walls changes under the occurrence of a magnetic field normal to the velocity of flow such that for large Hartmann numbers the variation of the velocity profile takes place only in a thin wall layer. The authors investigate the stability of such a flow relative to infinitesimal disturbances under the assumption that the magnetic Reynold number is  $R_m \sim 1$ , so that the range of high velocities and of temperatures from  $5000^\circ$  to  $10\ 000^\circ$  is included. From the linearized equations of magnetic hydrodynamics the authors obtain a system of two equations for the perturbations of the velocity of flow and of the field. By applying the asymptotic methods from (Ref. 6) then the authors succeed in extending the results of Lock (Ref. 5) for the case  $R_m \ll 1$  to the

TITLE:

Some Properties of Steady Flows in Magnetogasdynamics

PERIODICAL:

Zhurnal eksperimental'noy i teoreticheskoy fiziki. 1960.  
Vol. 39, No. 2(8), pp. 304-307

TEXT: The author theoretically investigates a steady linear or quasi-linear flow of an arbitrarily conductive medium (which is treated as a perfect gas) in a perpendicular magnetic field ( $u(H, u(u, 0, 0))$ ). From the initial equations of magnetogasdynamics, first the relations holding for a steady quasi-linear flow of a medium with  $\nu_m = 0$  ( $\nu_m$  - "magnetic" viscosity) are given, and in the following the case of a steady linear flow of a medium with  $\nu_m \neq 0$  is investigated. The initial equations (1) - (4) are again transformed for the specific case. Thermodynamic quantities (such as enthalpy  $w$ , and Joulean heat

Card 1/3

83177

Some Properties of Steady Flows in Magnetogas- S/056/60/039/002/014/044  
B006/B046

dQ - TdS) are introduced, and some relations are derived such as:  
 $(u^2 - a_m^2)de/q = p_m(k-1)m^{-1}(dh/dx)^2 dx = (k-1)dQ$ , and (16):  $udu + dw + bdn = 0$ ;  
 $u^2/2 + w + bdn = u_m^2/2 + w_m = A = \text{const.}$  ( $a_m$  is the effective velocity  
sound,  $w_m$  - the effective enthalpy at  $p_m = 0$ ,  $k$  - the ratio of specific  
heats;  $q$  - density,  $m = qu$ ,  $b = -ce_0/m$ ,  $e_0 = e$ ). Equation (12) is found to  
be analogous to the well-known equation of classical gas dynamics for the  
motion of a viscous gas in a heat-insulated tube of constant cross section.  
As also in this case heat conduction is neglected, the analogy is com-  
plete. From the fact that the right side of (12) can be only positive it  
follows that  $de < 0$ ,  $du > 0$  at  $u < a_m$  and  $de > 0$ ,  $du < 0$  at  $u > a_m$  (17).  
A continuous passage through the critical velocity value  $u = a_m$  is not  
possible. The case  $u = a_m$  is then more closely investigated, and it is  
shown by means of (12) and (17) that, under certain conditions, the forma-  
tion of a shock wave is possible in a medium of finite conductivity. Th<sup>X</sup>

TITLE: Plane laminar flow of a non-Newtonian liquid in a transverse magnetic field

SOURCE: Magnitnaya gidrodinamika, no. 4, 1965, 61-66

TOPIC TAGS: MHD flow, laminar flow, nonnewtonian flow

ABSTRACT: Two-dimensional laminar magnetohydrodynamic flows of a class of non-Newtonian liquids (so-called viscose-plastic flows) are studied. This flow is considered to be in a shallow flat channel with nonconducting walls. A uniform magnetic field is applied normal to the flow. The flow is caused by an applied pressure and the resulting pressure gradient in the flow direction. The equations describing the flow are solved to obtain the velocity profile. The motion of a central core of the fluid, behaving as a solid body is also derived on the pressure gradient and on the value of the magnetic field, as well as on the operating regime of the flow. The conditions which must be satisfied in order for the flow to become New-

TITLE: Effect of magnetic plasticity in non-Newtonian liquids

SOURCE: Magnitnaya gidrodinamika, no. 3, 1966, 69-75

TOPIC TAGS: non Newtonian flow, conductive fluid, Couette flow, flow velocity

ABSTRACT: Characteristics of non-Newtonian conducting fluids are investigated under conditions of applied electric and magnetic fields in the generalized regime described by the rheological power law. Hartmann and Couette flows are considered in detail since they yield analysis. It is shown that the characteristic dimensionless parameter in such problems is the generalized Hartmann number  $M$ . This number contains typical flow velocity and is influenced by the exponent value in the power law. For fluids with the exponent less or greater than unity, the flow velocity determines  $M$  (in the opposite sense for the two cases). Only for unity exponent can the number  $M$  be used as velocity independent. The effect of the transverse magnetic field on the fluid flow is analyzed and it is shown that a critical number,  $M_{cr}$ , exists. For  $M > M_{cr}$  quasi-solid regions occur (i. e., liquid velocity is unchanged over the channel cross

TITLE: Single Phase Distributed "Sine" Windings for Fractional Horse Power Induction Motors (Odnofaznyye raspredelenyye "sinusnyye" obmotki asinkhronnykh mikrodvigateley)

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Elektromekhanika, 1958, Nr 11, pp 41-56 (USSR)

ABSTRACT: This article deals with winding designs of fractional horse power induction motors, excluding the shaded pole type. The two types of motor of particular interest from the standpoint of winding distribution are single-phase motors in which the auxiliary winding for resistance or capacitance starting is disconnected after starting, and capacitor motors with one or two capacitors which are left in circuit whilst running. The main requirements of single-phase distributed windings are then stated. The initial starting torque must be adequate, there must not be serious diminution in the starting torque at particular speeds as the motor runs up to speed, the windings must be easy to manufacture and must not require additional insulation, as may occur in two layer windings, and finally it is desirable that the span should be short as this helps to keep the size of the end windings down and helps to make the

Card 1/6

SCW/144-58-11-5/17

Single Phase Distributed "Sine" Windings for Fractional Horse Power  
Induction Motors

machine short. Single-phase distributed windings are usually classified into three main types: single layer, two-layer with coils of equal turns and special "sine" windings in which the coils contain an unequal number of turns. Winding diagrams of the three types of winding for a standard series low power motor used with starting resistance type AOLx-11/4 are given in Figs 3a, b and v. It will be seen from the diagrams that in motors in which the auxiliary winding is disconnected after starting, with the usual types of single layer and two-layer windings in order to make the best use of the active materials the auxiliary winding is allotted only a third (or sometimes a quarter) of the total number of slots and two thirds are occupied by the main winding. In capacitor motors in which the auxiliary winding remains connected to the circuit during running, it is advisable to divide the stator slots equally between the two windings. Although single layer windings are easy to make and fill the slots better than two-layer windings, they have the disadvantage of creating marked spatial harmonics in the m.m.f. curve.

Card 2/6

SOV/144-58-11-5/17

Single Phase Distributed "Sine" Windings for Fractional Horse Power Induction Motors

In two-layer windings using a shortened span of one third pole pitch there is no third harmonic in the m.m.f. curve of either the main or the auxiliary winding. In single layer windings the third harmonic disappears because the winding is distributed between two thirds of the total number of slots but its amplitude in the m.m.f. of the auxiliary winding is considerable. It will be seen from Table 1 that with the winding diagrams of Figs 3a and 3b the fifth, seventh and higher harmonics are also present in single layer windings. Recently so-called "sine" windings have come to be used in single-phase fractional horse power induction motors. These windings are so-called because the distribution of the conductors in the slots is such as to ensure that the spatial distribution of m.m.f. is approximately sinusoidal and so therefore, is the induction in the machine air gap. This article does not consider the effect of tooth harmonics on the flux distribution in the air gap. In "sine" windings the conductors of both main and auxiliary windings are distributed between all the slots on the stator circumference. An advantage of the "sine" type winding is that all the coils of each of Card 3/6 the windings are in one layer only, and it is preferable to

SOV/144-58-11-5/17

Single Phase Distributed "Sine" Windings for Fractional Horse Power  
Induction Motors

keep the starting winding in the upper layer. It is, of course, difficult to make coils with different numbers of turns but there are advantages that fully compensate for this. A winding diagram of a "sine" winding for a motor type AOLB-11/4 is given in Fig 3a. The principal theoretical assumptions in designing "sine" windings for single-phase fractional h.p. induction motors are then considered. An ideal sine-wave distribution of conductors around a stator surface is of course impracticable. However, as will be seen from the diagrams in Fig 5, several approximations are possible that improve the m.m.f. wave shape and the most favourable is a trapezoidal distribution of conductors, as shown in Fig.6. The presence of slots naturally complicates the distribution, nevertheless, the conductors can be distributed in the slots in such a way that the m.m.f. curve is practically sinusoidal. With ordinary distributed windings simple formulae are available for calculating the amplitude and winding factors of higher harmonics but the matter is much more complicated in

Card 4/6

SOV/144-58-11-5/17

Single Phase Distributed "Sine" Windings for Fractional Horse Power  
Induction Motors

special "sine" windings with different numbers of turns. Curves of the spatial distribution of m.m.f. are then derived, see Figs 7a and 7b. Selection of the best distribution of conductors in the slots is then considered. Various cases of conductor distribution in the slots are considered with reference to Figs 9, 10, 11, 12 and 13. The m.m.f. curve approximates most closely to a sine-wave when the distribution is trapezoidal as shown in Figs 12 and 13. The best distribution is one in which the third harmonic is absent and the fifth and seventh are small. The necessary winding condition is expressed as a formula and Appendices 1 and 2 consider the application of the conditions to particular examples. The method of obtaining the m.m.f. distribution is then explained. The procedure of designing "sine" windings is then described. Table 2 gives pole pitch values for various numbers of poles and slots. The table is examined and winding conditions are deduced. The initial data required for the design of "sine" windings are then listed, and the order in which the various design steps should be made

Card 5/6

SOV/144-58-11-5/17

Single Phase Distributed "Sine" Windings for Fractional Horse Power  
Induction Motors

is described. Winding factors for "sine" windings are given  
in Table 3. There are 16 figures, 3 tables and 3 Soviet  
references.

AUTHORS: Pavlov, Kir Veniaminovich, and Somikhina, Galina Sergeyevna, Candidates of Technical Sciences, Docent (see Association)

TITLE: Calculating sinusoidal windings in single phase asynchronous miniature machines

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Elektromekhanika, no. 2, 1962, 177 - 188

TEXT: The article gives methods of calculating winding coefficients which are defined as ratios between the amplitude of harmonic mmf to the corresponding amplitudes in an equivalent lumped coil winding, spread exactly over one pole pitch. The author gives a general equation for winding coefficients for an even and odd number of slots per pole and compares the trapezoidal mmf curves with the curves for 'lumped' coil which are rectangular. The general equation for winding coefficient of the  $n$ th harmonic is

Card 1/3

Calculating sinusoidal windings ...

S/144/62/000/002/006/007  
D289/D301

$$k_{ov} = \frac{f(x_0) + \sum_{x_n} \Delta f(x_n) \cos v x_n}{f(x_0) + \sum_{x_n} \Delta f(x_n)} \quad (8)$$

where

$$0 < x_n < \pi/2.$$

The author considers the most favorable winding distribution. To obtain nearly sinusoidal mmf distribution, 3rd, 5th and 7th harmonics should be eliminated. Equating the above Eq. (8) to zero for a given harmonic a function of the distribution is obtained. In practice the trapezium distribution is often used where 1/3 of the slots/pole is filled with maximum number of conductors, the rest of the slots being filled with less. The author gives formulas for  $k_{ov}$  for various number of slots/pole and the mmf distribution. Distribution of turns in a coil is considered and also space for auxiliary winding apart from main windings. The author gives calculation of winding impedances, the general formula for reactance of main or

Title : The Leather Industry of German Democratic Republic

Orig Pub : Legkaya prom-st', 1956, No 5, 57-61

Abstract : Some specific features of the leather industry of German Democratic Republic are described. Faces and legs of cattle hides are cut off at the meat processing plants and the resulting byproducts are utilized in the production of food. Pig skins are removed only in the form of butts. Insole leather is produced only from sole leather splits and from pig skins but not from cattle hide butts. In the production of rigid leather use is made of circulation method of liming, tanning mixture contains up to

50% of high grade syntans, finishing and output of sole leather only in half butts. In the production of top leather use is made of short liming of yuft; chrome tanning with increased amounts of Cr<sub>2</sub>O<sub>3</sub> and reduced coefficients of liquid, retaining a certain amount of swelling of the dehaired hides, in the absence of NaCl; in the tanning of yuft are utilized up to 100% syntans, a wide range of finishing materials and yuft of greater thickness is manufactured. From pig skins leather of the "Kuhn" type is made, with ironed and cut surface to simulate kidskin, and velours. In the manufacture of all kinds of leather use is made of a wide and diversified assortment of standardized products, which are produced especially for the leather industry (softeners, tanning agents, dyes, emulsifiers, fats, finishing materials).

TITLE: Across Szamos and Tisza (Cherez Samosh i Tissu)

PERIODICAL: Nauka i zhizn', 1959, Nr 3, p 69 (USSR)

ABSTRACT: Recently a 365 km gas pipe line leading from the vast natural gas resources of Rumania to Hungary across the Egyedilap lowlands and the rivers Szamos and Tisza has started operation. The pipes have a diameter of 300 mm and operate under a natural pressure of 20 atmospheres. They will supply Budapest with gas and the industrial district of Borsod with fuel for the Tiszapalkony TETs, as well as the Metallurgical Combine imeni Lenin in Miskolcz. Thus Hungary will obtain 200 million cu m of methane annually, which means an economy of 1 million tons of local lignite.
