TITLE: On the influence of an air filter rubber hose during
simulating on models of an hydraulic shock.
(K vliyaniyu rezinovogo shlanga s vozdukhom pri modeli-
rovanii gidravlicheskogo udara).

PERIODICAL: Izvestiya Akademii Nauk SSSR, Otdeleniye Tekhnicheskikh
Nauk, 1957, No.11, pp.160-166 (USSR)

ABSTRACT: In earlier work published by one of the authors (Refs.1
and 2) the theory was evolved of hydraulic simulation on
models of non-steady state movements inside pressure
systems. Four similarity criteria were derived for the
general case and two criteria for the conditions of
hydraulic impact, i.e. for the ordinary case of dis-
regarding the friction and the ratio of the speed of flow
to the speed of the shock wave as compared to unity.
From the obtained relations and from the condition that
all the time constants should be equal in the nature and
in the model, it follows that the geometrical scale
 $\alpha = 10$ to 20 , i.e. the speed of the shock wave should
be considerably slower in the model than in the natural
Card 1/3 object. This condition imposes the necessity of simulating

TITLE: Concerning V.L. Inosov's Paper. (Zamechaniya k stat'ye V.L. Inosova, Russian)
PERIODICAL: Avtomatika i Telemekhanika, 1957, Vol 18, Nr 3, pp 282 - 283 (U.S.S.R.)
Received: 4 / 1957 Reviewed: 6 / 1957
ABSTRACT: The conditions suggested by V.L. Inosov in Avtomatika i Telemekhanika, 1954, Vol 15, Nr 4 concerning the stability of a system of any degree of complicatedness could be widely applied for the projecting of regulations only for the reason that hitherto there exists no computation method for the static stability limit of complicated energy systems. The following three main errors in the work by Inosov are enumerated: As the first point especially the physical importance of the function I occurring in the presence of an essential asymmetry in the coefficients C is stressed, and it is shown that the theorems for the investigation of the stability of the energy systems given in the first part of the work are not applicable in the case of automatic controls existing therein.
In point 2 it is stated that Inosov identifies the conditions for the positive amount of energy dispersion on the occasion of forced oscillations with the condition for a positive

TITLE: An Approximate Method of Studying Self-Oscillatory Systems Subject to Random Perturbations (Prilishennyy metod issledovaniya avtokolebatel'nykh sistem pri nalichii sluchaynykh vozdeystviy)

PERIODICAL: Izvestiya Akademii Nauk SSSR. Otdeleniye Tekhnicheskikh Nauk. 1958, Nr. 3, pp 14-24(USSR)

ABSTRACT: The work is an extension of Booton's and Barret's work on statistical linearization to systems which can perform stable self-oscillations (nonlinear systems). The usual equations for the linear and nonlinear links of such systems are used, employing operational methods. Various types of input noise spectra are considered (normal distribution, white noise, noise with upper or lower frequency bounds). Special consideration is given to real (bounded) nonlinear elements, such as relay automatic control systems (without backlash), and blocking oscillators. The transfer coefficients of systems with certain typical nonlinearities (ideal relay, relay with an insensitive zone, ditto with backlash, bounded linear amplifiers) are tabulated in a convenient form. The lack of suitable tabulated functions in many cases is stressed. Graphs of certain particularly important functions (on very

TITLE: Effect of an External Varying Slow Action on Ortho-Vibrating Systems (Avtokolebatel'nyye sistemy pri nalichii medlenno menyayushchikhsya vneshnikh vozdeystviy)

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh nauk, Mekhanika i mashinostroyeniye, 1959, Nr 1, pp 158-161 (USSR)

ABSTRACT: A method of calculation of the dynamic properties of an artho-vibrating system being affected by an external varying slow action is described. It is assumed that the latter can be defined as a function of time. The dynamic equation of the vibrating system with one non-linear term can be expressed as Eq.(1), where $Q(p)$, $P(p)$ and $N(p)$ - linear differential operators, z - regular normal process. It is also assumed that an ortho-vibration exists when $z = 0$ and that $z(t)$ represents a process with the mathematical expectation equal to 0 with the probability of being variable equal to 1 (Eq.(2), where T - period of ortho-vibration). The solution of Eq.(1) can be defined as a periodic sum x , y , and of slowly varying components x_2 , y_2 (Eq.(3)). Both components represent a function of time. It is further assumed

Card 1/6

DDI/179-53-1-27/36

Effect of an External Varying Slow Action on Ortho-Vibrating Systems
that Eq.(1) satisfies a condition of harmonic linearity. Then
 $x_1 = A \sin \omega t$ (Eq.(4)) and y can be expressed as the first
term of a Fourier series:

$$y = q_0(A, x_2) + q_1(A, x_2) x_1 \quad .$$

The periodic components can be taken as Eq.(5), or, for the
slow variations, the components Eq.(6). As the amplitude A
is changing slowly, its equation will take a form Eq.(7),
which can be considered as a relationship of the amplitude A
and a slow varying component x_2 (Eq.8). This can be ex-
pressed as Eq.(9). Then the transmission coefficient
 $q_0(A, x_2)$ will be expressed by x_2 only and Eq.(6) will take
the form Eq.(10). In order to find a solution for Eq.(10) it
is necessary to introduce $\partial q_0 / \partial A \equiv 0$ at $x_2 = 0$ so that
Eq.(11) can be found (A should be substituted by the amplitude

Card 2/6

174-53-1-27/36

Effect of an External Varying Slow Action on Ortho-Vibration, 37 (case of ortho-vibration A_0). The linear statistical equation of a slowly approaching component can be based on the normal equation:

$$\phi(x_1) = \frac{1}{\sqrt{2\pi}\sigma_x} \exp\left(-\frac{x_1^2}{2\sigma_x^2}\right)$$

where σ_x - mean deviation of x_2 . Then Eqs.(12) and (13) can be expressed for the mathematical expression of $x_2 = 0$.

As an example an accelerometric system is considered (Fig.1, where 1 - excitation coil, 2 - magnet, 3 - electronic commutator, 4 - switches, 5 - power source). The system is applied for measuring of acceleration of a flying object affected by the atmospheric turbulence. The dynamic properties of the system can be expressed as Eq.(14), where x - angle of inclination of the excitation coil, z - effective acceleration, T_1 - damping constant of coil, T_k - electric constant of coil, T_2^2 - inert constant of coil, k_1, k_2, k_3 -

Card 5/5

SOV/179-59-1- 2/36

Effect of an External Varying Slow Action on Ortho-Vibrating Systems
 - transmission ratios. The non-linear characteristic $f(x)$
 of the electronic commutator is shown in Fig.2. The values
 of ω and A for $z = 0$ are calculated as:

$$\omega = \omega_0 = \sqrt{\frac{c}{a}} \quad , \quad A = A_0 = \frac{4k_1}{\pi} \frac{a}{bc - ad} \quad ,$$

and the acceleration due to wind component is expressed as:

$$z(t) = hv(t) \quad .$$

The velocity $v(t)$, found experimentally, can be considered
 as a random function (Ref.4). It can be defined as a correla-
 tion function $R_v(\tau)$ for $\tau \leq 15$ as shown in Fig.3 (1 -
 turbulent distortion, 2 - approximate value). The solution
 of Eq.(14) can be expressed as $x = x_2 + A \sin \omega t$. From
 Eq.(8) the formula (15) is found, from which it is evident

Page 4/5

SOV/179-59-1-27/36

Effect of an External Varying Slow Action on Ortho-Vibrating Systems that $x_2 \leq A$ (Eq.(16). The linear expression, Eq.(17), is based on Eq.(11). The formula for mean deviation σ_x contains a term $S_z(\omega)$ which is a spectral density of $z(t)$. The order of computation is as follows: first the Eqs.(18) and (19) are found from Eq.(15), next the value of q_0^* , based on Eq.(17), is determined. Assuming that the distribution of x_2 is normal, the calculation of $q_0(\sigma_x)$ and $J_1(\alpha)$ are derived from Eq.(13) (the value of $J_1(\alpha)$ is shown in the form of a graph in Fig.4). Thus, from Eq.(14), the formula for σ_x is obtained as follows:

$$\sigma_x^2 = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{k_3^2 [T_k^2 \omega^2 + 1] S_z(\omega) d\omega}{[-b\omega^2 + d + k_1 q_{st}(\sigma_x)]^2 + \omega^2 [-a\omega^2 + c]^2}$$

The mean value of amplitude and the values of $J_2(\alpha)$, $J_3(\alpha)$, $J_4(\alpha)$ (Fig.5) are found from the formula at the bottom of

TITLE: The Application of ¹⁶Markov Chains to Calculate the Steady-State Error of Extremal Regulators,

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh nauk, Energetika i avtomatika, 1960, Nr 3, pp 64-72 (USSR)

ABSTRACT: The problem posed in this work is close to that of Ref 2 with new results mainly concerning the steady-state operation. The dynamic characteristics of extremal-regulation system are defined by their behaviour in the transient process (searching for the extremal) and in the steady-state (maintaining the system close to the extremal against the influences of noise and movement of the extremal position itself). The present article considers extremal regulators of the stepwise type. The executive organ of such systems carries out alternately two types of motion: test motions, to determine the partial derivative of the output variable with respect to the input (or its sign), and a corrective step on the basis of the results obtained in the test step. In such systems there are both systematic and random errors.

The Application of Markov Chains to Calculate the Steady-State Error of Extremal Regulators

Errors due to the characteristics of the controlled object may be compensated by using a computer which compares the output signal with the input signal after passage of the latter through a computer constituting a dynamic model of the system. If the system characteristics themselves are varying this cannot be realized exactly. The errors arising from this and from noise have a random character. To simplify the analysis, a linear model is assumed in which the test and working steps displace the object to a series of discrete points at fixed distances along a single axis. The number of the points is finite due to the finite range of the executive organ. The probability of a step in either direction is independent of the previous history of the system and is defined only by the coordinates of the point characterizing the operation of the system at a given moment. The problem thus reduces to a one-dimensional random walk and may be described in terms of Markov chains. The problem is to determine the optimal

The Application of Markov Chains to Calculate the Steady-State Error of Extremal Regulators

amplitude of the test steps corresponding to a given noise level. If these steps are made larger the probability of a false determination of the correct direction of the working step is reduced but, at the same time, the displacement from the extremal introduced by the test step itself increases. Two special cases are analysed: piecewise-linear characteristic and parabolic characteristic. Further, the influence of the time expended in the test steps is analysed. For this problem the test steps are assumed to constitute harmonic oscillations in the presence of white noise. With these assumptions, it is found that the probability of a correct step approaches arbitrarily close to unity as the period of test oscillation increases without limit. A more realistic model takes into account a linearly increasing systematic noise (non-stationary noise). In this case increasing the time constant of the test motion may lead to increasing deviation from the extremal. The present

analysis assumes a constant extremal characteristic. To analyse systems in which the extremal coordinate changes during the time of search will require the use of non-homogeneous Markov chains for which suitable mathematical apparatus does not yet exist. In an appendix, the probability of a step is calculated for two examples; the test steps are a sequence of discontinuous displacements of fixed amplitude; the test signal is harmonic. TITLE: The Search Time in Discrete Extremum Control Systems ⁹

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh nauk, Energetika i avtomatika, 1960, No.5, pp.87-95

TEXT: The search time is the time required to pass from some initial position to a required region close to the extremum. It is a random quantity dependent on the values of the coordinates involved. The present article considers a system with constant step for search over a piecewise-linear characteristic and is a further development of work by A.A.Feldbaum (Ref.1). It is assumed that the error values are uncorrelated random quantities with mathematical expectation equal to zero. This implies that the correlation time of random noise acting during the measurements is less than the duration of the measurement interval and that the basic time constant of the control process is much smaller than the interval between working steps so that the dynamic error may be neglected. It is pointed out that S.Serdengecti (Ref.2) has successfully solved the probability estimate of error taking into account object inertia. The basic method for the investigation is Card 1/2

E140/E435

The Search Time in Discrete Extremum Control Systems

that of Fuller on random walk. Furthermore, the problem is considered of searching with a step length proportional to the derivative - the gradient method. It is found that the estimate of dynamic properties of such systems only on the basis of the mathematical expectation of the search time is not always possible since the latter does not characterize the noise immunity of the system. Finally, the case is considered of a very small working step. Comparison of results shows that the mathematical expectation of search time for systems with a constant step is more sensitive to variation of the noise level than that calculated for a system with proportional search. A system was constructed on an analogue computer using a low-frequency noise generator and satisfactory agreement with calculations was found. There are 1 figure, 1 table and 7 Soviet references (1 a translation from English).

TITLE: Parametric Phenomena in the Simplest Continuous Extremal Control System a

PERIODICAL: Avtomatika i telemekhanika, 1960, Vol. 21, No. 9, pp. 1250 - 1253

TEXT: The present paper deals with the simplest inertialess system with a high-frequency noise at the input of the object. It is a continuous control system which seeks and maintains the extreme value of the characteristic of the inertialess object in the presence of intense random noise. This noise is in the frequency band containing the frequency of the trial periodic action. The accompanying figure shows the block diagram of the system. The parabola $y = -x^2$ is assumed to be the characteristic of the object. Next, equations are written down for the object, the demodulator, and the switching member. It is shown that the inclusion of a parameter in the equation that describes the coordinate x of the switching member is required by the high-frequency

noise at the input of the object. This parameter is variable with time. The method described in the paper of Ref. 3 is also used here, but the error is corrected. The conditions for the maintenance of stability are derived. The error was mentioned by V. I. Osorin in the periodical "Mekhanika", 1959, No. 10. The results obtained in the present work were experimentally verified by Ye. P. Gil'bo. Though the problem to be solved was very simple, it was possible to obtain a certain physical result that is valid for all continuous extremal systems based on the method of gradients. The result is the following: A consideration of random noise makes it necessary to treat the problem of stability of such systems more closely than has been done, e.g., in the paper of Ref. 4. Finally, it is noted that if there is a high noise level at the input of the object, control of the "tracking" of the extreme value may become impossible due to the parametric noise. There are 1 figure and 4 Soviet references.

TITLE: On linearisation by the method of distribution functions for problems in the theory of non-linear oscillations

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye tekhnicheskikh nauk. Mekhanika i mashinostroyeniye, no.5, 1962, 118-128

TEXT: The problem is to determine approximately the polyharmonic solutions of non-linear equations of the type

$$Q(p)y + R(p)x = S(p)z, \quad y = f(x) \quad (p \equiv \frac{d}{dt}) \quad (1.1)$$

where: $Q(p)$, $R(p)$ and $S(p)$ are polynomials in the operator p ; $f(x)$ is a non-linear function; z is a given function of the time (harmonic or polyharmonic). The method of harmonic linearisation, in which

$$x = a \sin t \quad (1.2)$$

and

$$f(x) \approx qx \quad (1.3)$$

Card 1/ 3

On linearisation by the method of ... S/179/62/000/005/007/012
E031/E135

and the method of linearisation proposed by Ya.G. Panovko, can both be regarded as particular cases of a more general method of linearisation, differing in their choice of distribution function. A periodic or almost periodic solution is obtained from the linearised equation resulting from the substitution in (1.1) of $qx_0 + r$ (x_0 is the difference between x and its mean value); q and r are obtained from the conditions that

$$J = \int_L [f(x) - qx_0 - r]^2 w(x, a_1, \dots, a_e) dx \quad (2.4)$$

has a minimum ($w(x, a_1, \dots, a_e)$ is the distribution function). The required solution can always be written in the form

$$x = a_0 + \sum_{i=1}^n a_i \sin(\omega_i t + \theta_i) \quad (2.7)$$

where $a_0, a_i, \omega_i, \theta_i$ are functions of the a_k . The a_k are

Card 2/ 3

On linearisation by the method of ...

S/179/62/000/005/007/012
E031/E135

conveniently taken as the moments of the distribution function and only the first two are usually needed - $\alpha_1 = m_x$ (the mean), and $\alpha_2 = \sigma_x^2 + m_x^2$ (where σ_x^2 is defined by

$$\sigma_x^2 = \int_L x_0^2 w(x, \alpha_1, \dots, \alpha_e) dx. \quad (2.5)$$

If $m_x = 0$, then $r = 0$ and $q = q(\sigma_x)$ and the equation

$$\sigma_x^2 = \frac{1}{2} [a_1^2(\sigma_x) + \dots + a_n^2(\sigma_x)] \quad (2.12)$$

can be used to determine σ_x . Knowing σ_x , the coefficients a_i can be found.

In the final section, using the method of Van der Pohl, the stability of polyharmonic solutions found by the above method is considered from the equation

$$\ddot{x} + b\dot{x} + f(x) = A_1 \sin(\omega_1 t + \psi_1) + \dots + A_n \sin(\omega_n t + \psi_n) \quad (3.1)$$

There are 6 figures.

TITLE: On the stability of solutions obtained by the method of statistical linearization

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye tekhnicheskikh nauk. Mekhanika i mashinostroyeniye, no.1, 1963, 184-189

TEXT: The method of statistical linearization is the most effective for the approximate solution of stationary regimes in nonlinear feedback systems. The present article examines the solution of equations of the type

$$Q(p)Y + R(p)X = S(p)Z, \quad Y = f(X) \quad (p = d/dt) \quad (1)$$

where Q, R and S are polynomials and Z a stationary random process. The problem reduces to the solution of two, in general transcendental equations having one or several solutions, corresponding respectively to stable or unstable regimes. Whereas the method of harmonic linearization (describing functions) has
Card 1/3

On the stability of solutions ...

S/179/63/000/001/028/031
E140/E135

been extensively studied, in the case of statistical linearization the problem of the stability of solutions has not even been posed. The problem consists in the examination of the behavior, as $t \rightarrow \infty$, of the solutions of an equation for the variance of the initial solution, i.e. a linear equation with variable coefficients constituting random functions of time. For equations of order higher than first, no methods are known for solving such a problem. However, in view of the degree of approximation of the initial method, it would appear that it would suffice if it were possible to determine whether the mean value and the dispersion of the variance remain bounded as $t \rightarrow \infty$. The method given here for obtaining this more approximate solution employs the basic assumption that the probability distribution of the variance is the same as that of the initial solution. A Volterra's integral equation is obtained, and solved by means of the Laplace transform. Two examples are worked, one in which

$$(p^2 + 2n p)X + f(X) = Z \quad (35)$$

where f is an odd function, and

AUTHOR: Iovlev, Yu. A.; Pervozvanskiy, A. A.; Savchikov, V. K.; Chelpanov, I. B.TITLE: Suppression of the harmonic content of a signal by means of a system of self-tuning filters 25

SOURCE: Leningrad. Politeknicheskii institut. Trudy, no. 235, 1964. Dinamika i prochnost' mashin (Dynamics and strength of machines), 79-90

TOPIC TAGS: low frequency, narrow band filter, filter stability, self tuning filter, harmonic suppression

ABSTRACT: Suppressing the harmonic content of a signal by means of a system of self-tuning filters requires the construction of a system of narrow-band wave-traps possessing the amplitude-frequency characteristics shown in Fig. 1. of the Enclosure. After presenting the system of differential equations describing the behavior of a system of self-tuning filters, the authors introduce the basic variants in the block diagram of the filter system. Two variants of feeding signals across the inputs of the filters are discussed: the fundamental signal is fed across the filter input, or the fundamental signal is combined with the outgoing

Card 1/3

L 26687-65

ACCESSION NR: AT5002369

signals from the other filters. In addition, four variants are discussed for controlling the filters. Then a static calculation of the filter system is carried out for the two latter variants: the filters are independent, and each filter is controlled by its outgoing signal and the sum error signal. The work of two filters for one harmonic content is then analyzed. It is concluded that two filters ensure a theoretically accurate compensation of the harmonic signal. The effect of small perturbations on the stability of two filters tuned to one harmonic content is then determined. The results obtained enabled the authors to solve the problem of the work of the two filters when the incoming signal consists of two harmonic components. From this, the author determines the work of an arbitrary number of filters when the incoming signal contains any number of harmonic components. Orig. art. has: 12 figures and 37 formulas.

TITLE: Abstract pattern recognition as a problem of linear programming

SOURCE: AN SSSR. Izvestiya. Tekhnicheskaya kibernetika, no. 4, 1965, 41-44

TOPIC TAGS: pattern recognition, linear programming

ABSTRACT: The formulation of the pattern recognition problem given here is similar to that presented by M. A. Aizerman, M. M. Braverman, and L. I. Rozonoer (Avtomatika i telemekhanika, v. 25, no. 6, 1964) where the potential functions method was proposed for solving the problem. It is shown that the problem of determining the hyperplane by which the input situations can be separated into two classes (pattern recognition problem) can be considered as a linear programming problem and can be effectively solved by known methods. The procedure of solving the pattern recognition problem by linear programming methods is described. It is also shown that these methods make it possible, in a finite number of iterations, to establish whether the input situations can or can not be separated into classes. TITLE: Evaluating the effect of linearizing normal random signals

SOURCE: Leningrad. Politekhnicheskiy institut. Trudy. no. 252. 1965. Dinamika i prochnost' mashin; mekhanika i protsessy upravleniya (Dynamics and durability of machines; mechanics and processes of control), 147-152

TOPIC TAGS: statistic analysis, electronic signal, normal distribution, linear approximation, nonlinear automatic control, linear automatic control

ABSTRACT: Certain rules are set for transforming normal random signals by passing through nonlinearities of sufficiently general nature. The mean, or expectation, value of a signal m_x is defined in terms of the mean as well as the mean-square value of the input values

$$m_x = m_x(m_s, c_s).$$

This expression for m_x is then Taylor-expanded in m_s and expressed as

$$m_x = \sum_{n=0}^{\infty} c_n \left(\frac{m_s}{c_s}\right)^n$$

Card 1/3

L 11932-66

ACC NR. AT5028842

where the coefficient c_n is given by

$$c_n = \frac{1}{\sqrt{2\pi} n!} \int_{-\infty}^{\infty} f(\alpha) e^{-\frac{\alpha^2}{2}} H_n(\alpha) d\alpha$$

Upon an integration by parts of c_n , one has

$$m_n = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(\alpha + m_n) e^{-\frac{\alpha^2}{2}} d\alpha$$

where c_1 , in particular, represents the amplification factor. To show that this linearization can be applied to a wide class of nonlinear problems and to evaluate the linearization domain, an odd function $f(z)$ is selected, and the following ratio is evaluated

$$\max \left| \frac{c_2}{c_1} \right|$$

The conditions under which the calculations are carried out are given by

$$\left. \begin{aligned} f(z) &= 1 \text{ at } z > k; \\ 0 < f(z) < 1 \text{ at } 0 < z < k; \\ f(-z) &= -f(z). \end{aligned} \right\}$$

The analysis leads to the determination of the extrema of the integral

$$I_n(f) = \int_{-\infty}^{\infty} f(\alpha) e^{-\frac{\alpha^2}{2}} (\alpha + M) d\alpha$$

Cont 2/3

L 11932-66

ACC NR: AT5028842

The final expression obtained is then

$$\Delta = \frac{m^2}{\sigma^2} \max \left| \frac{e_3}{c_1} \right| = \frac{m^2}{\sigma^2} \max \left(\frac{1}{6} \left| \frac{k^2}{\sigma^2} - 1 \right|; \frac{1}{6} \right) =$$

$$= \begin{cases} \frac{1}{6} \cdot \frac{m^2}{\sigma^2}; & \frac{k}{\sigma} \leq \sqrt{2}; \\ \frac{1}{6} \cdot \frac{m^2}{\sigma^2} \left(\frac{k^2}{\sigma^2} - 1 \right); & \frac{k}{\sigma} > \sqrt{2}. \end{cases}$$

which for $\Delta = 0.1$ leads to the fact that the nonlinearity is approximately linearized if

$$\sigma^2 > \frac{1}{0.6} m^2; \quad \sigma^2 > \frac{k^2}{2}$$

Orig. art. has: 25 equations.

PURPOSE AND COVERAGE: This monograph deals with procedures for finding hidden periodicities in various oscillatory processes. The book is intended for a wide range of specialists engaged in the mathematical description of oscillatory processes on the basis of observation data (oscillograms and other data). It is assumed that the readers have the usual Soviet engineering mathematics background and some knowledge of the theory of random processes and mathematical statistics. 16,44,55

TITLE: Considering the Influence of Systematic Deformation
of Aerial Photographs (Uchet vliyaniya
sistematicheskoy deformatsii aerofotos"yemochnykh materialov)

PERIODICAL: Geodeziya i kartografiya, 1959, Nr 4, pp 21-23 (USSR)

ABSTRACT: In the differentiated evaluation of aerial photographs for the
preparation of maps by the stereophotogrammetric method, the
differences in altitude on the topographic stereometer are

determined by the formula
$$h = \frac{H}{b + \Delta p} \cdot \Delta p$$
 . H is the

flying height over the initial point of the pair of aerial
photographs (stereophotographic pair), b is the basis of
photographing at the scale of the initial surface of the pair
of aerial photographs. Δp is the difference of the longitudinal
parallaxes. To increase the accuracy of the photogrammetric
procedure in determining the heights, the values contained
in this formula must be correctly used. The influence of
systematic deformation of aerial photographs

Card 1/2

Considering the Influence of Systematic Deformation
of Aerial Photographs

SOV/5-59-4-6/20

is investigated for this purpose. The systematic deformation of the aerial photograph (of the aernegative) can be represented geometrically as a change in the scale of the aerial photograph, at a corresponding change of the focal distance and an unchanged flying height. It is shown that H must also be free of distortions caused by systematic deformation if one wants to obtain an h-value not distorted by the influence of systematic deformation. It is shown that the values of b and Δp should not be corrected because of the systematic deformation. The flying height H, however, must be indicated in the same system as the difference in altitude h. It is pointed out that the formulas contained in the regulations for topographic surveys on scales of 1 : 10,000 and 1 : 25,000 should be corrected from this point of view.

Fermentation of cellulose. A. Alexopoulos and V. Chelrova. *Biotechnol. Prog.* 3, 36 (1983). The authors used Langwell's fermentation process so as to obtain a max. yield of alc. instead of AcOH. The thermophilic bacteria were isolated from horse manure and grown on a selective medium contg. filter paper and mineral salts. In the course of 20 months, by making fresh transfers, the cultures considerably increased their capacity to ferment cellulose rapidly. The speed of fermentation was increased 5-fold, and a max. yield of alc. was obtained (about 25%, after fermentation for 3 days) when MgCO₃ was substituted for CaCO₃ as the neutralizing agent. Besides AcOH, there were at times found as much as 25% of formic acid (by weight of fermented cellulose) and 14% of butyric acid. In old cultures, the amt. of formic acid largely decreases, often completely disappearing. Butyric acid is usually present in very small amts. in the first half of the fermentation period, whereas old cultures contain as much as 10-14% of the acid. A high lactic acid content is a sign of poor fermentation. H. Cohen

Formation of gluconic acid during the oxidation of glucose by bacteria. V. V. Pervozvanskii. *Microbiology (U. S. S. R.)*, No. 2, 149-50 (1969), cf. C. A. 36, 4489.

—P. found a parallel between the relation of 48 strains of fluorescing bacteria with quinic acid and their inability to take part in the fermentation processes. All strains formed org. acids in the presence of CaCO₃. In different bacteria these acids were identified as gluconic and 2-ketogluconic acids. After 13-70 days the amt of Ca gluconate in cultures was 23.4-77.4% of the initial amt of glucose. Formation of gluconic acids in *Bacterium putidum* L. et N. V. V. Pervozvanskii and M. A. Ivashkevich. *Ibid.* No. 3-4, 339-52.—Gluconic acid was the main product of the oxidation of glucose by *Bact. putidum* L. et N. The optimum conditions of the oxidation were temp. 30°, concn. of glucose 2.0% (up to 10% with air blowing), presence of CaCO₃ and a source of N. The process was greatly accelerated by an increase of the amt. of the inoculating material, by air blowing and by periodic mixing. The yield of pure Ca gluconate with air blowing and a 10% concn. of glucose was up to 87.0% of the glucose consumed. The method of oxidation of glucose by means of fluorescing bacteria can be used for large-scale production of gluconate. Through *Khim. Referat. Zhur* 1959, No. 11, 43. W. R. Henn

Formation of *d*-mannonic acid during oxidation of fructose by certain strains of *Bacterium fluorescens*. V. V. Koryukovskii. *Mikrobiologiya* (U. S. S. R.) 8, 015-30 (in English, 1969 11(1969)), of C. A. 34, 732163. —The possibility of biochem. oxidation of fructose without breaking the C chain was tested on 17 strains of *Bact. fluorescens* L. and N. (1), 5 strains of *Bact. putidum* L. and N., 2 strains of *Bact. pycnosporum* L. and N., 2 strains of *Bact. synonymum* L. and N. and 1 strain of *Bacillus pasteurii* Lang. Cultivated on 2% fructose in the presence of CaCO₃, only 12 strains of I produced 20-50% cal. Ca salts, mostly over 40% of the initial amt. of fructose. These salts were pptd. as flaky or jellybed sediments by treating with alc., the purified and condensed (as *resina*) cultural liquid. The Ca salts contained 12-13% FeCl₃ and did not reduce

Feibling's soln. The Ca salt produced by strain No. 8 of I was studied in detail. The chief product was *d*-mannonic acid. From its purified Ca salt, contg. 12.12% CaO, the *phenylhydrazide*, m. 210°, and a brucine salt, m. 281°, *loilo* = -27.8°, were prepd. Decompd. with a calcd. amt. of oxalic acid and crystal from alc., a mixt. of the lactone of *d*-mannonic acid with Et mannionate was obtained, m. 142-43°, *loilo* = +24.4°, on standing and heating, +32.2°, with HCl, +42.5°, mean equiv. wt. 198. Other derivatives: *γ-lactone*, m. 151.5°, *loilo* = +52.3°, equiv. wt. 172, *cryst. Ca salt*, (C₁₁H₁₇O₆)Ca 2H₂O, contg. 12.07% CaO, *loilo* = -7.1° (dehydrated), *brucine salt*, m. 285°, *loilo* = -20.5°, *quinine salt*, m. 165°, *loilo* = -100°. Reduced by Na amalgam to *d*-mannose, its *phenylhydrazide* was obtained, m. 188-9°, on recrystn. from 60% alc., m. 281°. The Ca salts obtained from cultures of other strains of I were also transformed into *γ*-lactone and identified. The results show that in all 12 acid-forming strains the product of breaking oxidation is *d*-mannonic acid, obtained without breaking the C chain. By the action of bacterial suspensions on fructose solns. under aerobic and anaerobic conditions a series of strains produced substances oxidizable by iodine in an alk. medium (Wallstatter and Shull), but it is unknown whether the formation of *d*-mannose or gluconic acid. Formation of *d*-gluconic acid along with *d*-mannonic acid was not observed, which indicates the presence of optically active catalysts produced by the bacterial cells during the oxidation process.

TITLE: Ferroprobe Defectoscope

PERIODICAL: Zavodskaya laboratoriya, 1960, Vol. 26, No. 11, pp. 1301-1304

TEXT: An apparatus is described, which is used to detect defects in small steel products having the shape of rotating bodies. The specimens are magnetized outside the device and then placed near two probes whose signals are transmitted to the separator via an amplifier. Fig. 2 shows a diagram of the two series-connected probes. 1, 2 denote the cores of 80HXC (80NKHS) permalloy wire, 0.1 mm thick. I: exciter coil, II: search coil, 3Г audio-frequency generator, 3B tube voltmeter, M specimen, B its magnetic field. The second harmonic of the emf is selected in the circuit. Fig. 3 shows the scheme of the separator. 1 denotes a rotating brass pipe driven by the engine 4, which transports the specimen to the probes 2. 3Г is the audio-frequency generator, 3 the amplifier, 3 the separator with separating magnet 5. There are 3 figures.

Title : Problems Pertaining to the Study of Tannin Bearing
Plants

Orig Pub : Botan. zh., 1956, 41, No 9, 1407-1409

Abstract : The results of studies of conferences on plant
resources of the USSR, conducted in 1954, and on
cultivation of new useful plants, conducted in 1956
under the auspices of the Botanical institute, Acad.
Sci., USSR are explained. It is indicated that the
tannin-extracting industry must increase the planned
production of tannides in the sixth five year period by
25% in comparison with 1954. Along with non-marketable

oak wood pulp, the industry utilizes presently the
bark of spruce, willow, larch, roots of bistort, sea
lavender, rhubarb (chukhra) and leaves of smoke tree
in small quantities. It is necessary to strengthen
the coordination of studies of tannin bearing plants
between various scientific-research institutions and
to improve their connection with production organiza-
tions. It is necessary to develop a speedy and
accurate method of quantitative determination of
tannins. Attention is drawn on increasing work with
grassy tanning plants. The conference showed the
necessity of introduction into commercial cultivation
in Uzbekistan and in the Southern Kazakhstan of
tanning bistort. It is recommended to investigate the
