Smelting of Tube Steel by the Scrap Process from a Low-manganese Iron at Different Manganese Practices

the manganese content of metal by additions of ferro-manganese does not protect the boiling bath from over-oxidation and leads to a contamination of steel by non-metallic inclusions. 3) Under normal conditions of pure boiling (with normal slag and reduction of manganese) and using low-sulphur fuel smelting of steel by the scrap process from low-manganese pig and without ferromanganese additions is not accompanied by a decrease in the degree of dephosphorisation and desulphurisation of metal or by a deterioration in the strength and plastic properties of steel (in particular, at negative temperatures, up to  $-60^{\circ}\text{C}$ ). 4) The degree of oxidation and desulphurisation of steel and the proportion of rejects and mechanical properties of metal are independent from the absolute content of manganese in the metal during the course of smelting. 5) The investigation confirmed that the change introduced into the technological instruction, i.e. that the manganese content in metal during the course of smelting, including the period of pure boiling, does not necessarily need to be strictly controlled, is rational. N.I. Lebedkin, B.P. Okhrimovich and others, members of the staff of the Works and Institute participated in the work. There are 5 tables, 8 figures and

AUTHORS: Petrov, K. M., D'yakonov, V. A.

TITLE: Vacuum treatment of open-hearth furnace alloy steel

PERIODICAL: Stal', no. 4, 1961, 383

TEXT: At the kombinat im. A. K. Serova (Integrated Plant imeni A. K. Serov) a great amount of open-hearth alloy steel was produced in a 90-ton ladle at a residual pressure of 3 - 8 mm pressure/merc. ccl. When vacuum-treating the metal jet during pouring over from one ladle to another, in this case of non-reduced WX<sup>15</sup> (ShKh<sup>15</sup>) steel, melted in an acid open-hearth furnace with an addition of 45%-ferrosilicon and aluminum the amount of oxide inclusions of a 90-mm<sup>2</sup> ingot is reduced to 0.50 points. The whole melting process has been cut down to 30 minutes by carrying out the oxidization process directly in the vacuum installation and not in the furnace. The globular inclusions were reduced to 0.40 points by oxidization with calcium-silicon and vacuum treatment of the molten metal jet. the life of ball bear-

ings made from vacuumized ShKh15 steel increases by 70%. Rejects of the steel grade 38XMOA (38KhMYuA) due to surface rejects could be reduced from 14.0 to 6.45% by vacuum treatment of the steel in the ladle. No flake formation could be noticed in 37XC (37KhS) steel, which also was vacuum-treated. At the Chelyabinskiy metallurgicheskiy zavod (Chelyabinsk Metallurgical Plant), vacuumized siphon pouring was applied in the casting of steel ingots of the 18XHBА (18KhNVA) steel grade, weighing 1,15 kg. Improved macrostructure and reduced reject rates due to intercrystalline cracks have been achieved. ✓

TITLE: The Don Main Canal in Service (Donskoy magistrall'-nyy kanal vveden v deystviye)

PERIODICAL: Gidrotekhnika i melioratsiya, 1959, 4, pp. 14-18 (USSR)

ABSTRACT: The authors give data on the newly constructed second section of the Don Main Canal project (85 km in length). The total length of the first two sections is 112 km. As for the project's third section, the Proletarskaya vetv' (Proletarskaya arm), its construction has just started. The new canal now constitutes a single water system along the valleys of the river Sal, the western stretch of the river Manych, and the lower Don. It will perform the following functions: 1) irrigate 40,000 hectares by the Bogayevskiy and Sadkovskiy main canals; 2) irrigate 13,500 hectares by the Proletarskiy arm; 3) soften the Sal river water and water some 80,000 hectares and 4)

maintain the Veselovsk reservoir water level and making its water softer in order to supply the Asov main canal, with its irrigation area of 1000 hectares, in operation. The Don Main Canal starts at the Tselnyanskoye reservoir and ends by flowing into the Dnieper valley. Its capacity varies between 100 m<sup>3</sup>/sec at the start and 80 m<sup>3</sup>/sec, reaching at the siphon point 110 km. The earth-moving work has been fully mechanized. The following figures are quoted to illustrate the work volume of the project's second section: 1) total volume of earth moved - 29,000,000 m<sup>3</sup>; 2) total volume of concrete and reinforced concrete - 133,000 m<sup>3</sup>; 3) total weight of metal frames - 78,000 tons, and 4) total area of paved surface - 106,000 m<sup>2</sup>.

TITLE: Use of water diving investigations and aerial methods to study the underwater vegetation of seas

SOURCE: AN SSSR. Okeanograficheskaya komissiya. Sektsiya podvodnykh issledovaniy. Razvitiye morskikh podvodnykh issledovaniy (Development of underwater marine research). Moscow, Izd-vo Nauka, 1965, 34-41

TOPIC TAGS: aerial photography, ocean floor topography, underwater photography, photo interpretation

ABSTRACT: In discussing the virtues of underwater investigations of the sea by means of diving suits and aqualungs the author points out that this method has its faults owing to poor horizontal visibility under water, difficulty of movement, limited stay in the water, and the small areas of the sea bottom that can be investigated. However, this method can be supplemented by aerial photography of the sea bottom. The value of aerial photographic surveying is that it accurately depicts the contours of the underwater plant cover of large bodies of water.

Card 1/3

04067-67  
ACC NR: AT6024957

Maximal information on the plant cover of the marine bottom is obtained from aerial photographs only when the structure of the underwater landscape as a whole is taken into account when interpreting the photographs. The primary task of interpretation is to distinguish the boundaries of natural complexes on the photographs. This is accomplished in two stages. At first the areas characterized by different types of images are outlined. Individual natural complexes have specific morphological features and can be recognized by the character of the images on the aerial photographs. Then the final and reliable interpretation of the boundaries of the natural complexes is done during field (marine and water diving) investigations. Details of the structure of the underwater vegetation within natural complexes, ecotopes, revealed by aerial photographs, are studied directly on the marine bottom by diving. The purpose of the underwater investigations is to learn the characteristics of the phytocenoses, to describe the environmental conditions, and reveal the patterns in the distribution of the phytocenoses. Three methods of underwater work are recommended: 1) the investigated body of water is covered with a network of stations which are scattered or arranged in rows along certain routes. At the point of observation the ship is anchored and a diver descends to the bottom and examines a region equal to the area of a circle having a radius of 100 m; 2) transectional lines are laid out along the marine bottom. The diver enters the water and, moving along a tape measure, makes his observations. The bottom is examined continuously and when necessary the diver signals the sloop to stop and the researcher studies the vegetation; 3) rectangular areas (100 x 200 m) are marked out on the bottom by tape measures and on the surface by buoys. The diver

Card 2/3

swims between the marked out lines and studies the vegetation. These underwater investigations are used to gather material for the interpretation of the aerial photographs. Orig. art. has: 4 figures.

**PERIODICAL:** Vestnik Elektropromyshlennosti, 1958, No.2, pp.69-72 (USSR)

**ABSTRACT:** This is a mathematical article on the calculation of temperature rise in a conductor during the passage of excess current for a brief period. The equations assume that no heat is lost during the process. Expressions are derived for the maximum and minimum values of the time integral of the square of the current. These may be written in different ways, depending on the conditions, and values of a constant entering into the equations are tabulated. By way of example, a calculation is made of the time required for a fuse to interrupt a circuit. Calculated and experimental results are compared in Fig.1. and good agreement is claimed. There are 4 figures, 2 tables, no literature refs.

Abstract : An experimental group of cows whose diet lacked the necessary amounts of proteins and vitamins, received the following concentrates starting with the last third of their pregnancy: 480-240 units of vitamin A; 50 thousand units of vitamin D, and 1 mg of vitamin E. In addition to their fodder, calves from these cows received 20 thousand units of vitamin A every 5-10 days, 50 thousand units of vitamin D once every 5 days, and 100-250 mg of ascorbic acid daily for the first 7 days of their lives. Control group did not receive any vitamins. In the experimental group calving required assistance during labor in 63.2 percent of the cases, in

Title: Analyzer of a fundamental speech tone

Source: Izv. Priberostroyeniye, v. 9, no. 5, 1966, 12-14

Topic TAGS: speech signal, audio signal analyzer

ABSTRACT: A device for observing fundamental speech tone is described. The CRT is used as a display unit. A vertical deflection oscillator is synchronized with the frequency of the fundamental tone and the oscillator output voltage, after being amplified by a paraphase amplifier, passes to vertical deflection plates. Horizontal deflection plates are fed by regular sawtooth pulses with a period of 1-10 sec. The speech signal is fed to the CRT cathode. An image of the speech signal is formed on the CRT screen. Horizontal variation denotes time; vertical variation, duration; and variations in brightness indicate the instantaneous value of the speech signal. Orig. art. has: 2 figures.

TITLE: The Problem of Vacuum-Degassing of Steel for Electrical Engineering Purposes

PERIODICAL: Tr. In-ta metallurgii. Ural'skiy fil. AS USSR, 1958, Nr 2, pp 67 - 72

ABSTRACT: The Institute of Metallurgy UFAN USSR together with the Verkh-Issetskii Plant investigated the effect of vacuum treatment on the quality of transformer steel smelted in a basic electric furnace. Vacuum treatment was carried out under laboratory conditions in a chamber containing a ladle of ~ 40 kg capacity filled with metal. The metal was kept in the chamber for 8 - 10 minutes with a vacuum of 97 - 98%. Experiments were carried out with vacuum treatment of liquid steel in a 500-kg mold during the siphon-filling process. The experimental mold was equipped with a flange in its upper section to fasten the cover. The mold

and 1/3

007/37-59-5-9971

The Problem of Vacuum-Degassing of Steel for Electrical Engineering Purposes

was filled within 2 - 2.5 minutes under violent effervescence of the metal. The vacuum was on the average 425 mm Hg. Under industrial conditions, vacuum treatment was performed in a chamber holding a 20-ton ladle with liquid metal. During rarefaction of 650 - 700 mm Hg a violent gas liberation occurred during 3 - 4 minutes, accompanied by a boiling of the metal and ascent of the slag. Ten minutes after vacuum treatment, bubbling continued only there where the slag contacted the lining of the ladle. Gases pumped out of the chamber contained  $CO_2$ , CO,  $H_2$  and  $H_2S$ . Heavy corrosion of the refractory lining of the ladle and the stopper coils was observed 8 - 10 minutes after the vacuum treatment began. This limited considerably the duration of the vacuum treatment. Metal subjected to vacuum treatment in a laboratory chamber, or during filling of the mold, showed a reduction of  $[H]$  and improved bending characteristics. It was noted that vacuum treatment of large metal masses did not considerably improve the quality of the metal. It is pointed out that this is caused by the secondary saturation of the metal with  $[H]$  during its contact with the refractories within the siphon. It was established that vacuum treatment of metal in a ladle promoted the refinement of the grain structure.

The Problem of Vacuum-Degassing of Steel for Electrical Engineering purposes.

steel. Conventional ingots had uniform transcrystallization, while vacuum-  
cast ingots had a uni-axial crystalline structure. As a result of vacuum  
treatment [H] was reduced by 25 - 40%, and the amount of non-metallic im-  
purities by 25 - 30%.

Poluprovodnikovyye pribory i ikh primeneniye; sbornik statey, vyp. II (Semiconductor Devices and Their Uses; Collection of Articles, no. 2) Moscow, Izd-vo "Sovetskoye radio," 1957. 398 p. No. of copies printed not given.

Ed. (title page): Fedotov, Yakov Andreyevich; Ed. (inside book): Ivanushko, N.D.; Tech. Ed.: Sveshnikov, A.A.

**PURPOSE:** This book is addressed to physicists and electronics engineers interested in semiconductor devices and their applications in electronics.

**COVERAGE:** This is a collection of articles on semiconductor devices and their applications. There is an insert containing a circuit diagram of the measuring instrument described in the article on p. 331. No personalities are mentioned. There are 84 references, of which 33 are Soviet (including 3 translations), 1 Swiss, 6 German, 42 English, and 2 French.

AUTHORS: Flerov, G. N.; Karmazukhov, V.A.; Ter-Akop'yan, G. M.;  
Petrov, L. A.; Subbotin, V. G.

TITLE: On proton decay of radioactive nuclei

SOURCE: Zh. eksper. i teor. fiz., v. 47, no. 2, 1964, 419-432

TOPIC TAGS: radioactive decay, proton decay, proton radiation,  
heavy particle, Coulomb repulsion force, alpha particle reaction

ABSTRACT: This paper is an elaboration of a previous report (ZhETF v. 45, 1280, 1963) and contains additional new data on observed proton emitters. Experiments on proton decay of radioactive nuclei, using the internal beam of the heavy-ion cyclotron of OIYaI, are described and data are presented on two types of proton emitters obtained by bombarding nickel with beams of  $Ne^{20}$  and  $O^{16}$ . The first (one of the light isotopes of neon or magnesium) has a half-life

Card 1/5

ACCESSION NR: AP4043611

$(85 \pm 15) \times 10^{-3}$  sec and emits protons with energy  $5 \pm 0.2$  MeV. The second has a half-life  $23 \pm 4$  sec and emits protons with energy  $2.5 \pm 0.2$  MeV. It is concluded on the basis of several experiments that the second emitter is one of the light isotopes of Kr or Br, so that sub-barrier protons are emitted (height of the Coulomb barrier is  $\sim 8.5$  MeV). It is most probable that the protons are emitted from the daughter nucleus following the positron transition with which the measured half-life is connected. The emission of  $\sim 5$  MeV protons is similar to the emission of delayed neutrons. The emission of 2.5-MeV sub-barrier protons is analogous to the emission of long-range alpha particles by heavy nuclei. It is also shown that in the case of the  $\sim 2.5$ -MeV proton emitter another possible mechanism is proton decay of configuration isomers. Further work is planned for an experimental determination of the mechanism of the observed proton decay and for a more exact identification of the obtained protons. "The authors are grateful to E. Z. Pyndina and her co-workers for much preparing the silicon detectors, which were
