"Amperometric Determination of Zinc in Brasses and  
Zinc Plating Baths," A. A. Popel', A. T. Marunina

"Zavod Lab" Vol XVI, No 6, pp 658-661

Describes procedure for determining zinc in brasses  
and electrolytes of acid and alkaline zinc plating  
by method of amperometric titration with potassium  
ferrocyanide. Determination takes 15-25 min and ac-  
curacy of method is sufficient for routine proxi-  
mate analysis.

*An amperometric determination of barium. A. M. Vasil'ev  
and N. A. Popov. Naučnyj Komitet Fiz.-Khim. Nauk. Akad. Nauk  
S.S.R., Otdel. Khim. Nauk 4(7), 126-34 (1952).—Ba was  
detd. by amperometric titration with  $K_2CrO_4$  in the presence  
of  $NH_4^+$ , acetate, K, Sr, and Ca ions. When the mole ratio  
 $NH_4Cl:BaCl_2$  was 100:1, or when the mole ratio  $KNO_3:Ba  
(NO_3)_2$  was 200:1 the results were good. As much as 1.5M  
of acetate ion did not affect the detn. The titration could  
be done at pH 4-7 but if Ca or Sr is present the necessary  
range is pH 5-6.5. At mole ratio Ca:Ba of 50:1 the  
error was within 1%. If the mole ratio Sr:Ba was 30:1, Ba  
could still be detd. but not with larger amts. of Sr. Ba  
could be detd. in the presence of both Sr and Ca if their mole  
ratio to Ba was not more than 50:1. The usual app. with a  
dropping Hg electrode was used. Titrations were at a poten-  
tial of 1 v. referred to the satd. calomel electrode. Ba could  
be detd. from 0.002M aq. solns. within an error of 1%.  
 $K_2CrO_4$  soln. was 0.5M for most titrations but 0.01M for  
dil. solns. of Ba.  $BaCrO_4$  ppt. was formed slowly so 5-20  
min. was required for establishment of the equil. current.  
Work with very dil. solns. was difficult. Below pH 4 the re-  
sults were low because of the solv. of  $BaCrO_4$ . Above pH 7  
results were low because some basic chromate of Ba was  
formed.*

Determination of the solubility of 8-quinolinol in mixed solvents. A. M. Vasil'ev, A. A. Popel and M. M. Prokhorova. Uchenye Zapiski Kazan. Univ. 113, No. 8, 75-81 (1953); Referat. Zhur., Khim. 1954, No. 38175.—The solv. of 8-quinolinol in water-acetone and water-alc. solns. at 20° was studied polarographically and amperometrically (A. A. Popel, ibid. 110, 4, (1050)). The concns. of  $\text{Me}_2\text{CO}$  and alc. were varied from 2.5 to 35 vol. %. The solv. of 8-quinolinol in  $\text{H}_2\text{O}-\text{Me}_2\text{CO}$  solns. rose sharply with the increase of  $\text{Me}_2\text{CO}$  concn. At 20%  $\text{Me}_2\text{CO}$  the solv. was 6 times as much as the solv. in  $\text{H}_2\text{O}$  and twice as much as the solv. in a 20%  $\text{H}_2\text{O}$ -alc. soln. The solv. of 8-quinolinol was also studied in  $\text{NH}_3$  solns. at 25°. The concn. of  $\text{NH}_3$  was varied from 0.4 to 4.9 mole/l. The dissoc. const. of 8-quinolinol detd. from its solv. in  $\text{NH}_3$  solns. was  $0.4 \times 10^{-11}$ . The effect of temp. and concn. of  $\text{NH}_4\text{Cl}$  on the solv. of 8-quinolinol was also detd. M. Hosh

Solubility and acid-base properties of 5,7-dibromoquinolinol. A. M. Vasil'ev, A. A. Popel, and G. P. Khodukova. Uchenye Zapiski Kazan Univ., 133, No. 8, 83-90 (1954); Referat. Zhur. Khim., 1954, No. 38170. — The solv. was detd. in 0.5-4.0N HCl, 0.5N HNO<sub>3</sub>, 0.5 × 10<sup>-2</sup>-0.5N NaOH. In the acids the solv. of 5,7-dibromoquinolinol increased w/ the concn. of the acid. In the alkali the solv. increased with the concn. of NaOH and reached a max. at 0.1N. From the solv. detn. was calcd. the dissoci. const. of 5,7-dibromoquinolinol as base ( $K_b$ ) and as acid ( $K_a$ ). The calcd. values were  $K_b = 2.15 \times 10^{-11}$  and  $K_a = 1.2 \times 10^{-9}$ . The pH at the 1/2-elec. point was calcd. to be 5.7. Solv. actn. were also made in 10-80% aq. Me<sub>2</sub>CO solns. and in pure Me<sub>2</sub>CO. At an Me<sub>2</sub>CO concn. of 10-20% the solv. of 5,7-dibromoquinolinol increases 5-10 times. Acidification of the H<sub>2</sub>O(Me<sub>2</sub>CO) solns. with HCl doubled the solv. M. Hesch. # 82

✓ Application of organic reagents for amperometric titration. A. A. Popel. *Ucheny Zapis Krem. Gossudarstv. Univ.*, 1956, v. 1, p. 73-76. Moscow-Leningrad, Khim. 115, No. 3, 60-82 (1956).—The literature on amperometric titrations with org. reagents is reviewed for detn. of K, Cu, Ag, Au, Mg, Ca, Zn, Cd, Al, Ti, Zr, H, Tb, Sn, Bi, Fe, Co, Ni, Br, and Bi be titrated with dianilopyrrolmethane in sulfate solns. contg. Cl or CNS complexes. Good results were obtained in Br solns. at potentials from -0.3 to -0.5 v. with 0.03-0.12 g./l. KBr. The same reagent also is usable for titration of Cd in acidic solns.

PERIODICAL: Uch. zap. Kazansk. un-ta. 1957, Vol 117, Nr 2, pp 184-187

ABSTRACT: Experiments were conducted with standard solutions of Sb  
with additions of a radioactive isotope. After creating a def-  
inite concentration of the halide, Sb is precipitated with an  
acid alcohol-water solution of diantipyrimethane (D). The  
most complete precipitation occurs in the presence of I<sup>-9</sup>  
(to 5·10<sup>-9</sup> g/ml). The precipitate is dissolved in an alcoholic  
solution of HCl (1N HCl and 50% of alcohol) and Sb is deter-  
mined polarigraphically. The excess of D has no effect on the  
height of the step. The error of the determination of Sb is  
<0.02 mg. 1. Antimony—Separation 2. Radioisotopes--

TITLE: Influence of the symmetry of a paramagnetic complex on the proton relaxation time

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 149, no. 3, 1963, 637-638

TEXT: The pH dependence of the transverse proton relaxation time,  $T_2$ , was measured for aqueous solutions of halides and nitrates of copper, cobalt, nickel, iron, manganese and chromium. With copper bromide solutions (ion concentration 0.4 mol) a rapid decrease from 4.5 to 2 seconds followed for  $T_2$  if the pH increased from 0.5 to 3. It is assumed that this effect is caused by a decrease in the symmetry of the complex entailing an increase of the relaxation effect of the copper ions. The assumption was confirmed by measurements of the effective g-factor of the  $Cu^{2+}$  ions: For the  $-\lg(H^+)$  values -0.35, 0.0 and 1.85  $\epsilon_{eff}$  2.177, 2.181, and 2.188 was derived. Also the change in the color of the solution from blue to brownish yellow indicates a change in the

Card 1/2

Influence of the symmetry of a ...

9/020/63/149/003/027/028  
B192/B102

symmetry of the complex. A similar decrease of  $T_2$ , if pH increased from 1.5 to 3, was observed for  $\text{CrCl}_3$  solutions with the color of the solution shading from violet into green. For chromium nitrate and copper nitrate no decrease of  $T_2$  with increasing pH was derived. It is assumed that the change of symmetry is due to the formation of hydroxide-halide complexes. For the  $\text{MnCl}_2$  solutions no decrease of  $T_2$  was derived, in agreement with theoretical considerations. There are 3 figures.

SOURCE: Jemna mechanika a optika, no. 2, 1964, 38-42

TOPIC TAGS: laser, resonator, helium emission, neon emission, helium spectrogram,  
neon spectrogram, stimulated emission, high frequency generator

ABSTRACT: The authors describe the construction and technology of a continuously emitting He-Ne (9:1) laser. A resonator was used consisting of two concave mirrors 50mm in diameter (radius of curvature - 800 mm) with 13 dielectric interference layers for a maximum reflective capacity at a wavelength of 1.1523  $\mu\text{m}$ . The setup for measuring the emission spectra is described. Three different shapes of tube were tested, differing in length, diameter, gas pressure, and the angle of closure. The first sign of stimulated emission was achieved with spherical mirrors at a distance of 860 mm; it appeared as a new emission line at a wavelength of 1.15  $\mu\text{m}$ . Various frequency patterns were observed, and the most typical ones were photographed; some of these photographs are reproduced in the paper. "In conclusion, the authors thank M. Rubes, K. Stefka

TITLE: A photoeffect with exciton participation

SOURCE: Ukrayinsk'kyy fizychnyy zhurnal, v. 10, no. 8, 1965, 925-926

TOPIC TAGS: exciton, internal photoeffect, photoionization, semiconductor band structure, forbidden band, light absorption

ABSTRACT: A method of elementary node excitations is used to include directly the effect of the interaction of various excitation branches and describe processes stimulated as a result of this interaction by an external electromagnetic field. Qualitative results are obtained by considering a two-band model of a semiconductor and a simple crystal in which all atoms in the normal state have two s electrons and the excited state is some nondegenerate p state. For a sufficiently wide forbidden band the method of node excitations is comparatively easy to apply. In the field of the light wave the excitation Hamiltonian can be described by a sum  $H_0 + W(t)$ , where  $W(t)$ ,

Card 1/2

0901 1024

L 4539-66

ACCESSION NR: AP5020696

3

treated as a perturbation, contains all terms describing the interaction with light. If the interactions among the quasiparticles are neglected, one obtains four terms; two of these correspond to the exciton absorption of light and the ordinary internal photoeffect. The two other terms and their conjugates describe new processes; the photoionization of Frenkel excitons is one of these and leads to an approximate expression for the absorption coefficient. The inverse process, expressed in the Hamiltonian by the conjugate term, is discussed. It is stated that the second process in which two excitons participate can be considered similarly. TITLE: Adhesion of very simple boric enamels to low-carbon steel.

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no.11, 1962, 150-155

TEXT: Although the use of  $SiO_2-Na_2O-B_2O_3$  with small additions of other components as the base for ground enamels is increasing, the effect of the main components on the strength of adhesion has not yet been studied. In the present work the adhesion of molten enamels to a polished surface of a 0.084% carbon steel was investigated. Adhesion was calculated from measured values of the surface tension of the melt and the contact angle. The surface tension was measured at 1000°C by the maximum argon bubble pressure method. Of the main components,  $B_2O_3$  had the greatest effect on adhesion; it substantially reduced interparticle bonding in the melt and its adhesion to both oxidized and unoxidized steel. Fig.2 shows the effect of other additions (abscissa, mol %;

ordinate, adhesion, erg/cm<sup>2</sup>) for the system  $67SiO_2-15Na_2O-18B_2O_3$

Method of measurement of the interfacial tension at high temperatures. S. I. Popel, O. A. Zin, and P. V. Gel'd (S. M. Kirov Ural Polytech. Inst., Sverdlovsk). Doklady Akad. Nauk S.S.R. 74, 1097-1100(1950).—The interfacial tension  $\delta$  is detd. from the height  $h$  (measured from the top to the equator of the drop) of a drop, photographed with x-rays, which permits photography of a drop of metal (15-25 mm.) in a fused slag. With  $\rho_1$  and  $\rho_2$  = d. of the metal and of the medium, resp.,  $\delta = \frac{1}{g} (\rho_1 - \rho_2)gh^2$ , where  $g$  = acceleration of gravity. The method was applied to drops of Hg (against air and against  $H_2O$ , at 30°), of Cu (against gas, at 1300°), and of cast iron (against gas, at 1400°). It gives generally too low values of  $\delta$  as compared with detns. with the aid of other equations, but close thereto. Frozen drops generally show  $\delta$  smaller by about 10% than in the molten state, which may give rise to deviations in  $\delta$  of ~14-33% with the d.s. taken as those of the solids, and of ~6-30% with the use of the d.s. of the fused substances. Consequently,  $\delta$  ought to be detd. in the

liquid state. The method is indicated for chemically aggressive or highly viscous substances. N. Thon.

Interphase tension of iron alloys at the slag interface  
S. I. Popov, O. A. Kulin, and P. V. Gel'd (S. M. Kirov Ural  
Polytech. Inst., Sverdlovsk), *Doklady Akad. Nauk  
SSSR*, 73, 227-30 (1950); cf. *C.A.*, 45, 2743k.—A previously described method was used to det. the interphase tension between molten Fe alloys and slags. A pig iron contg. C 3.46, Si 2.21, Mn 0.64, P 0.26%, and S 0.105% had at 1420° a surface tension with gas of 1022 erg./sq. cm. and interphase tensions of about 630, 700, and 750 erg./sq. cm. with slags contg. 9, 14, and 50%  $\text{Al}_2\text{O}_3$  (plus 47% CaO, balance  $\text{SiO}_2$ ). A synthetic Fe alloy contg. 4.0% C and 0.4% Si had at 1480 to 1550° a surface tension with gas of 675 and interphase tensions of about 550, 600, and 610 with slags contg. 16, 27, and 39% CaO (plus 26%  $\text{Al}_2\text{O}_3$ , balance  $\text{SiO}_2$ ). When  $\text{Na}_2\text{O}$  replaced about 3% of  $\text{Al}_2\text{O}_3$  in the 39% CaO slag, the interphase tension at 1400° dropped to about 500, and when  $\text{Na}_2\text{O}$  completely replaced the  $\text{CaO}$  the value became 410. A synthetic slag replaced the  $\text{CaO}$  in the 39% CaO slag, the interphase tension at 1420° to contg.  $\text{SiO}_2$  48,  $\text{CaO}$  28, and  $\text{Al}_2\text{O}_3$  20% had at 1420 to 1510° interphase tensions of about 600, 510, 480, and 260 with Fe alloys contg. Si 0.4, C 4.8; Si 8.0, C 2.8; Si 20, C 2.6; Si 40, C 0.2%. The results are explained by the ionic theory of slags on the basis that cations and anions of the slag which have a large ratio of charge to radius will strongly adhere to each other and displace ions with weak fields from the surface layer. surface energy of the alloy. Substitution of Fe by Cr, i.e., conversion of ferrosilicon to ferro-silicon chromium, is accompanied by a very slight rise of the interphase tension. The very low interphase tension at the boundary of the silicon-silicate melt is explained by the formation of SiO, which lowers the energy differential between the phases in contact and favors of unification their structurally similar elements.

Electrocapillary phenomena at different compositions of metal and slag. Yu. P. Nikitin, O. A. Esin, and S. I. Popel (C. R. Acad. Sci. U.R.S.S., 1952, 87, 813-815).—Electrocapillary phenomena in the system liquid Fe-C alloy-slag are investigated. Exchange of CaO for Na<sub>2</sub>O in the slag causes lowering of interphase tension,  $\delta_m$ , along the whole course of the cathode branch of the electrocapillarity curve. It follows that on the boundary of Fe-C or Fe-P alloys and slags the surface activity of Na ions is higher than that of Ca ions. P is also a surface-active agent but it lowers  $\delta_m$  to a smaller degree than equal at.-% of C. Whilst adsorption of C decreases with the increase of cathode potential, the adsorption of P does not depend upon it. S. K. LACHOWICZ.

Title : Calculation of surface tension by the form of a recumbent drop

Periodical : Zhur. fiz. khim. 28/9, 1678-1679, Sep 1954

Abstract : A table for the calculation of surface tension according to the form of a recumbent drop and a suitable method for the graphical integration of an equation for such a drop are briefly described. The method, which has numerous advantages, is also applicable to drops of different size and form. Examples of such calculations are shown. "The Surface Activity of Carbon and Phosphorus at the Metal-Slag Interface"

Tr. Ural'skogo Politekhn. In-ta, sb. 49, 1954, 82-86

Interfacial tension of iron-carbon and iron-phosphorus alloys with synthetic slag was determined by photographing drops lying on a corundum block and correlating the results with X-ray data. Established that as the carbon and phosphorus content is increased, the interfacial tension is decreased. The effect of phosphorus is less than that of carbon. Interfacial tension of above alloys is close to that of the surface tension. Interfacial tension of iron-carbon alloy with carbide slag was estimated using the cooled drop method, and found to be less than the surface tension of the slag. (RZhKhim, No 3, 1955)

PipeL, S. I..

Surface tension of simplest oxide systems. S. I. Popel  
and O. A. Esin (Ural Polytech. Inst., Sverdlovsk). *Zhur.  
Fiz. Khim.* 30, 1103-201 (1956). — The max. bubble pressure  
was identical whether N or Ar was used as the gas and was  
nearly independent of the rate of bubbling (a few bubbles  
per min.) but a little different for different capillaries; the  
total error of the surface tension ( $\sigma$ ) values was 6%. The  
 $\sigma$  of FeO 97, Fe<sub>2</sub>O<sub>3</sub> 3 wt. % (apparently at about 1400°) was  
500 ergs/eq. cm. and was lowered to 500 when the concn.  
of Fe<sub>2</sub>O<sub>3</sub> rose to 8%. In melts of FeO-Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> at  
1340-1400°,  $\sigma$  was higher, the higher was the concn.  $c_1$  of  
FeO, when the concn.  $c_2$  of SiO<sub>2</sub> varied between 7 and 30%.  
In the MnO-SiO<sub>2</sub>-FeO system at 1400°,  $\sigma$  decreased when  
 $c_1$  increased (between 20 and 45%). The effect of 1-7%  
CaO on the  $\sigma$  of FeO-Fe<sub>2</sub>O<sub>3</sub> melts at 1350-1400° was small,  
and  $\sigma$  was 430-480. The  $\sigma$  of FeO-Fe<sub>2</sub>O<sub>3</sub> melts at 1300-  
1400° was lowered by Na<sub>2</sub>O, e.g., to 350 when  $c_1$  was 50%  
and the Na<sub>2</sub>O content was 15%. Substitution of CaO for  
FeO in ferrous silicates at  $c_1 = 21$  to 25% had little effect on  
 $\sigma$ . The effect of temp. between 1350 and 1400° was small.  
The results are accounted for by the potential energy of the  
ionic interaction. J. J. Bikerman

TITLE: The Surface Tension and Densities of the Simplest Oxide Systems  
(Poverkhnostnoye natyazheniye i plotnosti prosteyshikh oksidnykh sistem)

PERIODICAL: V sb.: Fiz.-khim. osnovy proiz-va stali. Moscow, AN SSSR.  
1957, pp 497-504. Diskus.. pp 505-512

ABSTRACT: The surface tension  $\sigma$  of molten oxides was measured by the value of the maximum pressure in the bubbles. This was the method used to determine the densities of the silicate melts. The experiments were carried out at temperatures of  $1340^{\circ}$ - $1400^{\circ}$ . The crucibles, capillaries, and tubes were prepared from Fe. N<sub>2</sub> served as the working gas. The surface tension of FeO with a 6.3% Fe<sub>2</sub>O<sub>3</sub> content was 590 ergs/cm<sup>2</sup>. When the Fe<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub> contents were increased, the surface tension declined evenly, reaching 400 ergs/cm<sup>2</sup> as the SiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> contents reached 30.5% and 4.8%, respectively. The density of FeO at  $1400^{\circ}$  equaled 4.90 g/cm<sup>3</sup>. The addition of SiO<sub>2</sub> caused a drop in density such that, when the SiO<sub>2</sub> content reached 30%, the density fell to

Card 1/2

137-1958-2-2361

**The Surface Tension and Densities (cont.)**

3.67 g/cm<sup>3</sup>. The dependence of the specific volume on the composition was almost of a straight-line character, which showed how near an FeO-SiO<sub>2</sub> system comes to being an ideal one. When in MnO-FeO-SiO<sub>2</sub> alloys SiO<sub>2</sub> was substituted for the MnO portion the surface tension declined in a straight-line fashion from 517 ergs/cm<sup>2</sup> when the SiO<sub>2</sub> and FeO contents were 19.8% and 21.3 %, respectively, to 400 ergs/cm<sup>2</sup> when they were 45.0% and 23.7%, respectively. In CaO-FeO-SiO<sub>2</sub> alloys of orthosilicate composition the surface tension was 410-440 ergs/cm<sup>2</sup>, changing but little when FeO was introduced in place of CaO. By contrast, the density in that event declined from 4.0 to 3.23 g/cm<sup>3</sup>. The specific-volume curve against percent CaO (mol) followed a concave upward path.

TITLE: Surface Tension of Fused Silicates. (Poverkhnostnoye natyazheniye rasplavlennykh silikatov.)

PERIODICAL: Zhurnal Neorganicheskoy Khimii, 1957, Vol.II, Nr.3,  
pp. 632-641. (USSR)

ABSTRACT: Although detailed information is available on the surface tension of oxidizing slags, the same cannot be said of blast-furnace types of slag. The few values that are available show great discrepancies and fail to show the effect of composition. In the present investigation the surface tension of CaO - SiO<sub>2</sub> - Al<sub>2</sub>O<sub>3</sub> and CaO - SiO<sub>2</sub> - MgO melts were determined by two independent methods: maximal pressure in a bubble, and stationary drop. At 1750°C the surface tension of silica was only about 400 erg/cm<sup>2</sup>, rising with addition of alumina. A rise was also observed when silica was replaced by lime, but the introduction of magnesia

TITLE: The Effect of Components Dissolved in Iron on Its Interphase Tension with Slag (Vliyaniye komponentov, rastvorennykh v zheleze, na yego mezhfaznoye natyazheniye so shlakom)

PERIODICAL: Tr. Ural'skogo politekhn. in-ta, 1957, Nr 67, pp 60-63

ABSTRACT: A measurement is made of the interphasic tension  $\sigma$  of Fe and of ferroalloys at the metal (ME) - slag (SL) boundary. A thin plate of fused magnesia is placed on the bottom of a graphite crucible, and on it rests a drop of ME immersed in SL. The crucible is subjected to X-rays and a shadow image of the drop is produced on a film. An enlargement yields its true dimensions.  $\sigma$  is determined therefrom by means of graphs. The ME used was of technical purity. The SL was of chemically pure oxides. Experiments with Fe-V, Fe-Si, and Fe-Ti employed SL of the following weight % composition; CaO 46, SiO<sub>2</sub> 36, Al<sub>2</sub>O<sub>3</sub> 18, while in the experiments with Fe-Mn and Mn-Si the SL were of the following composition (in % by weight): CaO 25, SiO<sub>2</sub> 65, Al<sub>2</sub>O<sub>3</sub> 12. The densities of the ME were

Card 1/2

137-58-6-11520

**The Effect of Components (cont.)**

calculated from their values at room temperature, on the assumption that their coefficients of expansion were the same as with steel containing 0.45% C. The densities of SL, as measured by the change in maximum pressure in the bubbles on immersion of the tube into the melt, are 2.80 and 2.66 g/cm<sup>3</sup>, respectively, for the first and second SL. The experiments were run at 1480-1560°C. The  $\sigma$  values of the Fe-Mn, Fe-Si, and Mn-Si alloys vary against concentration in virtually linear fashion and constitute 1200 and 1080 erg/cm<sup>2</sup> for Fe and Mn respectively, 710 erg/cm<sup>2</sup> for Fe-Si at 60 atomic % Si, and 700 erg/cm<sup>2</sup> for Mn-Si at 50 atomic % Si. In the alloys Fe-V and Fe-Ti the corresponding curves are bent slightly upward and drop to 400 erg/cm<sup>2</sup> at 27% Ti, and 480 erg/cm<sup>2</sup> at 38% V. The drop in  $\sigma$  in the case of Fe-Mn is explained by the adsorption of MnO, the concentration of which in the SL after the experiment was higher (up to 3.8%) than that of FeO (up to 1%). In the case of other alloys, the drop in  $\sigma$  is induced chiefly by the appearance of weaker bonds within the metal phase, e.g., as a result of the formation of quasi-molecules of FeSi and Fe<sub>3</sub>Ti. An increase in the concentration of Ti, V, Si, and Mn at the ME-SL boundary and the good solubility of oxides there-in in the SL ensures the oxidation of these additions in the steel-smelting furnace at the ME-SL surface.

Effects of sulfur on the phase boundary tension between metals and slags. S. I. Popel, O. A. Esp, G. P. Konyagin, and N. S. Smirnov (S. M. Kirov Ural Politecn. Inst., Sverdlovsk), Doklady Akademii Nauk S.S.R. 177, 1048 (1957). For the desulfurization of molten steel, and the behavior of slag inclusions in ingot casts the surface tension conditions on the phase boundary metal/slag are of primordial importance. S is known to decrease considerably the surface tensions, and to promote wetting characteristics on solid surfaces (cf. Kozakevich, et al., C.A. 49, 8063f). The authors used the same x-ray shadow-casting method previously described (C.A. 45, 2743b; 46, 5581f), pure Fe, FeS, and two synthetic slag compns., one similar to steel, the other to blast-furnace slags (with 35% and 47% CaO, 27.2% and 1.0% FeO, resp.) were fused in MgO or Al<sub>2</sub>O<sub>3</sub> crucibles. Dissolving of the crucible material did not affect the phase-boundary phenomena. The shape of the metal drops on the slag melts are considerably changed (flattened) if the S content in the metal is increased, the surface tension is decreased. At 1620° to 1670° the surface tension of pure Fe to the slags is 1015, and 700 ergs/sq. cm., and decreased to about 600 and 350 ergs/sq. cm., resp., if 2% S was added to the melt. The exp'l. results are important for the study of the transition of S from the metal melts into the slags, and explain the great stability of non-metallic inclusions in steel if they contain much S and FeO in the same time. Such emulsions do not easily coalesce because the electrokinetic potential impeding this process is considerably changed by the action of S (cf. Deryagin, C.A. 32, 9232f).

TITLE: Electrochemical Refining and Alloying of Ferrous Metals (Elektrokhimicheskoye rafinirovaniye i legirovaniye chernykh metallov)

PERIODICAL: V sb.: Staleplavil'n. proiz-vo, Moscow, Metallurgizdat, 1958, pp 151-161

ABSTRACT: A description is offered of the results of experiments in 1948-1952 in the electrochemical refining and alloying of metals. The laboratory experiments were run in a resistance furnace with a Silit electrode and in a 50-kg high-frequency furnace. Electrochemical refining of metal proved feasible. The application of an external electrical field to a metal-slag system makes it possible to regulate the speed and completeness of transfer of S from the metal into the slag. Pilot-plant experiments at the Verkh-Isetsk Plant employed a D-C generator (1000 amps, 120 v). The metal was poured into a 300-kg ladle. The results of the industrial experiments showed that when an external electrical field was applied the removal of

Card 1/2

SOV/137-58-9-18659

**Electrochemical Refining and Alloying of Ferrous Metals**

sulfur from the steel proceeds with considerably greater efficiency than without electrolysis. Depending upon the initial composition of the metal and the slag and upon the quantity thereof, the S content diminished by 0.020-0.045% during the first 10 min. Simultaneously with the removal of S from the metal, an increase in Si content was observed. Current efficiency was from 20 to 96%. The experiments demonstrated the desirability of further development of the method and of its introduction into industrial practice.

nonmetallic inclusions in ingots of rimming-steel de-  
oxidized by different methods. S. I. Popel, G. F. Kono-  
valov, and N. A. Butkevich (Metall Works, Seversk). 1958.  
*Vysshikh Ucheb. Zavedeni Chernaya Met.* No. 5,  
51-7.—A study was made of chem. and phase compn. of  
nonmetallic inclusions in 650-kg. ingots of 0.13-0.18% C  
rimming steel deoxidized in the furnace (a) with ferro-  
manganese, and (b) ferromanganese and ferrosilicon.  
The inclusions were extd. and studied in relation to their  
depth in the ingot. The results showed that introduction of  
ferrosilicon (2 kg./ton) decreases the amt. of inclusions to  
about  $\frac{1}{4}$ . Their phase compn. is also altered by ferrosili-  
con addns.: the content of high-m.p. inclusions, such as  
corundum and spinel, is decreased, while the quantity of  
low-melting silicates increases. Explanation of this is found  
in the nature of the emulsions formed. Introduction of  
ferrosilicon increases the emulsion concn. and lowers the vis-  
cosity of the dispersed phases and their adhesion to metal,  
thereby forming larger particles and facilitating their re-  
moval from the metal. 23 references. B. N. Daniloff

TITLE: On the Method of Measuring the Surface Viscosity of Silicate Melts  
(K metodike izmereniya poverkhnostnoy vyazkosti silikatnykh rasplavov)

PERIODICAL: Izv. Sibirsk. otd. AN SSSR, 1958, Nr 5, pp 66-73

ABSTRACT: A description of apparatus and methods employed in the determination of the surface viscosity ( $V_s$ ) of high-temperature silicate melts. The process is based on the method of damped oscillations ( $O$ ) of a disk which intersects the surface of the liquid. The vibrating device consists of an iron disk, 20 mm in diameter and 6 mm high, which is rigidly coupled to a rod by means of a special joint and is suspended by a nichrome wire. The joint carries a small mirror and a clamp for the wire; the upper face of the joint supports two iron plates in which torsional vibrations are induced with the aid of an electromagnet; the vibrations are registered on a graduated scale by means of a ray of light reflected from the mirror. The slag being investigated is charged into an Fe crucible, 50 mm deep and 50 mm

Card 1/3

SOV/137- 59-1-1516

**On the Method of Measuring the Surface Viscosity of Silicate Melts**

in diameter, and the crucible is placed into an electric Krypto! furnace. The temperature of the melt is controlled with the aid of an optical pyrometer; in order to achieve an inert atmosphere, N<sub>2</sub> is introduced into the hermetically-sealed furnace. The depth of immersion of the disk is determined by means of a control lamp mounted on the lifting mechanism. After the desired temperature had been attained, the crucible containing the slag is placed into the furnace which is then closed; the vibrating device is centered, the disk is immersed into the slag to a depth equivalent to half of its height, and torsional O's are induced in it. Depending on the V, the amplitude is recorded at intervals of one, five, ten or more O's, and from these O's the logarithmic surface damping decrement,  $\lambda_{\text{surf}}$ , is computed. After repeating this procedure five or more times the disk is immersed into the slag to a depth of 5 mm measured from its upper surface and the volumetric damping decrement,  $\lambda_{\text{vol}}$ , is determined. The relative value  $a$  of the V of the surface layer is determined from the ratio  $a = \lambda_{\text{surf}} / \lambda_{\text{vol}}$ ; in order to determine the absolute values of the V, the thickness of the surface layer must be known. The volumetric V is computed from the magnitude of the damping decrement of the disk O's within V is computed from the magnitude of the damping decrement of the disk O's within the slag. The apparatus is previously calibrated at a temperature of 20°C against standard liquids, such as water, mercury, and liquid paraffin. An investigation of the surface and volumetric V demonstrated that the surface layer of a number of

liquid slags exhibits an increased V; the latter increases when SiO<sub>2</sub> and Fe<sub>2</sub>O<sub>3</sub> are introduced into the FeO, or when MgO and Al<sub>2</sub>O<sub>3</sub> are added to the silicate melt.

TITLE:

The Effect of the Components of an Oxide Melt on Its Interfacial Tension With Iron (Vliyaniye komponentov oksidnogo rasplava na yego mezhfaznoye natyazheniye s zhelezom)

PERIODICAL:

Zhurnal fizicheskoy khimii, 1958, Vol 32, Nr 10,  
pp 2398 - 2402 (USSR)

ABSTRACT:

The influence of CaO, SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub> and FeO on the interfacial tension of iron and the oxide phase the composition of which is similar to that of simple furnace and steel-melt slags was investigated. The interfacial tension was determined according to a method described already (Ref 6) and an X-ray taken of the iron drop in the oxide melt at 1580°C. The changes of the interfacial tension ( $\sigma$ ) in dependence on the concentration of Al<sub>2</sub>O<sub>3</sub> and CaO is shown in a graph. The value for  $\sigma$  is high and in this system amounts to 1060-1290 erg/cm<sup>2</sup>; it changes little with the composition. This value increases a little

Card 1/3

Interfacial Tension With Iron SOV/76-32-10-24/39

in the exchange of  $\text{SiO}_2$  with  $\text{CaO}$  or  $\text{Al}_2\text{O}_3$ . This tends to show a strong attraction of the iron atoms among themselves and their low interaction with the ions of the slag. In further experiments the collaboration of G.F.Konovalov the influence of the iron oxide was investigated. With an increase of the iron oxide concentration an intense decrease in the interfacial tension was found. At 70%  $\text{FeO}$  in the slag the value  $\sigma$  amounts to only  $1000 \text{ erg/cm}^2$ . The iron oxide is therefore a surface active component with regard to the boundary metal-slag. This is explained by the effect of the oxygen in  $\text{FeO}$  as well as by the good solubility of  $\text{FeO}$  in the metal phase. The formation of the slag inclusions in steel is made easier by the reduction of the interfacial tension by  $\text{FeO}$  and these inclusions are thermodynamically more stable. Finally, the author thanks Professor O.A.Yesin. There are 1 figure, 2 tables, and 18 references, 16 of which are Soviet.

Engineer.**PURPOSE:** This book is intended for engineering and scientific workers  
of institutes and machine-building plants, as well as for students  
of advanced courses at universities.**COVERAGE:** This collection consists of articles dealing with practical  
problems in foundry processes. The articles review the achievements  
of Ural foundry workers in the past 40 years and present  
aspects of a current study on the casting of nodular cast iron.  
The properties and casting methods of a description is given of  
ceramic and architectural casting. Consideration is given to the  
problem of removing gases in steel and aluminum. The structure  
of cast steel is discussed. A recent investigation of vacuum  
casting including its characteristics and new applications  
is also presented. There are 32 pages of photographs, illustrations  
at the end of the book. No personalities are mentioned. References  
follow each article.

## TABLE OF CONTENTS:

Popel', S.I. Vettin Refractories With Molten Metal and Slag 162  
 The purpose of this study was to investigate the effect of carbon,  
manganese, silicon, sulfur, and phosphorus dissolved in  
iron on the setting of magnesia and other materials by the iron  
and to determine the magnitude of the contact angle formed by  
liquid slags on various surfaces. The method and results of the  
investigation are described. It is concluded that the magnitude  
of contact angle formed by the drop of commercially pure iron on  
magnesia surface is 115-120° and the angle formed by CaO-SiO<sub>2</sub>-  
Al<sub>2</sub>O<sub>3</sub> and CaO-Al<sub>2</sub>O<sub>3</sub>-MgO slags varies slightly with composition  
and the temperature of 1400-1750°C is equal to 112-125°. It  
is concluded that carbon, manganese, silicon, sulfur and phos-  
phorus dissolved in iron improve the setting of magnesia by  
iron.

TITLE: Nonmetallic inclusions in vacuumed ball-bearing steel with different methods of chromium alloying

SOURCE: IVUZ. Chernaya metallurgiya, no. 10, 1964, 17-21

TOPIC TAGS: vacuum treatment, nonmetallic inclusion, carbon steel, chromium additive, quartz, tungsten additive, ball bearing steel, chromium alloying

ABSTRACT: Vacuum treatment of ball-bearing steel greatly improves quality but the problem of lowering the number of inclusions has been inadequately studied. Therefore, the authors undertook a study of the effects of vacuum refining carbon steel on inclusions and on their composition by using the method of Cr inoculation. The charge was composed of 150 g sponge iron with 0.05% C, 0.007% Si, 0.006% Mn, 0.005% S and 0.008% P, and 5 g crushed electrode. Metallic chromium (99.5% Cr) was added in batches of 0.5, 1 and 1.5%. Specimens were treated in a

Card 1/2

L 39764-65

ACCESSION NR: AP4047334

3

high-frequency vacuum furnace at 1585 C. After the completion of boiling Cr was introduced and the specimens subjected to furnace cooling. The second method consisting in charging Cr together with the iron into a cold furnace produced 50% less inclusions in the degassed Cr specimens. The content of wustite was 6-7%, quartz 53% and chromite and chromium oxide 60% lower. Cr added to degassed metal produced 0.050 to 0.082% (weight of steel) oxides. An increase in the amount of Cr did not change the number of inclusions. Orig. art. has 3 tables.

TITLE: Method of determining the rate of penetration of melts into capillary porous materials

SOURCE: Poroshkovaya metallurgiya, no. 8, 1965, 50-54

TOPIC TAGS: liquid metal, foam metal, electric conductivity, electric resistance, electrodynamics, iron oxide, silicon dioxide, magnesium

ABSTRACT: The method consists in continuous determination of the level of the melt in the sample by measurement of the electrical resistance. It is applicable to systems in which the electrical conductivity of the impregnated body is substantially different from that of the starting body. A study was made of the movement of melts of  $\text{FeO}-\text{SiO}_2-\text{Fe}_2\text{O}_3$  into pressed samples made of powders of fused magnesium at 1220-1420 C. The movement was measured with an automatic electrical potentiometer. The samples were cylindrical with a diameter of 20 mm and a height of 40-50 mm, pressed from a moist (7% water) mixture of pulverized

Card 1/2

L 64552-65

ACCESSION NR. AP5020770

fused magnesium of known particle size and refractory clay (9%). Porosity of the samples was 37.5-38.5% and was practically identical over the length. The percentage of open pores exceeded 99%. Simultaneous temperature measurements were made with platinum-platinum rhodium thermocouples. Results showed that the depth of penetration increases with time according to the parabolic curve  $l^2 = K \gamma t$ , where  $l$  is the length of the sample and  $K$  is the penetration constant which increases with a decrease in the proportion of silicon dioxide and with a rise in temperature.
