TITLE: Investigation of the adsorption properties and secondary
pore structures of adsorbents having the effect of micro-
filters. Communication 4. Granulated synthetic zeolites
of the A-type

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye khimicheskikh
nauk, no. 8, 1961, 1387-1395

TEXT: The authors investigated the adsorption properties, the secondary
pore structures of the grains and their apparent and gravimetric density.
Granulated A-type zeolites obtained by Soviet scientists at the beginning
of studies in the field of zeolite synthesis, were investigated. A number
of specimens by Ya. V. Mirskiy (Mr) were used, during the production of
which the pressure was repeatedly changed, and one specimen by
B. A. Lipkind (Lp). The designation of the samples is composed of the
abbreviated name of the producer and the specimen number given by him.

Two specimens each of granulated zeolites by the American firm of Linde (I) and (II) in the form of grains with 1/8" diameter were used for comparison. To the sodium form (NaA) belonged: Mr-296, Lp-202-2, Linde 4A (I), Linde 4A (II). To the calcium form (CaA) belonged: Mr-297, Mr-347, Mr-372, Mr-380, Linde 5A (I) and Linde 5A (II). The isotherms of sorption and desorption of benzene vapors were determined by sorption scales in vacuum. The specific method for experiments with zeolites was previously described by M. M. Dubinin (Ref. 3: Izv. AN SSSR, Otd. khim. n., 1961, 750). The isotherms determined had generally the same character as those mentioned by the authors, Ye. A. Leont'yev and V. M. Luk'yancvish (Ref. 2: Izv. AN SSSR, Otd. khim. n., 1961, 396). Adsorption isotherms of water vapors were measured by sorption scales in vacuum for direct comparison of the adsorption properties of granulated, completely dehydrated zeolites. The secondary pore structure of the grains was investigated by pressing in mercury, and according to the sorption method. Mercury porometry makes it possible to determine the distribution of the pore volumina according to their effective radii in the range of $1 \cdot 10^6$ to $15-25 \text{ \AA}$. From the isotherms of capillary condensation of vapors

Card 2/8

Investigation of the adsorption...

B117/B206

of substances, for which the pore structure of zeolite crystals (primary porosity) is inaccessible, sorption volumina or the summary pore volumina with effective radii below 100 Å might easily be found. From these data the total volume of the secondary pore structure may be calculated. In experiments with mercury, low- and high-pressure pore meters were used (Ref. 4: M. M. Dubinin, A. I. Sarakhov and G. A. Ryabikov, Zh. fiz. khimii 32, 1404, (1958); Ref. 5: M. M. Dubinin, M. M. Vishayakova, Ye. G. Zhukovskaya, Ye. A. Leont'yev, V. M. Luk'yanovich, A. I. Sarakhov, Zh. fiz. khimii 34, 2019 (1960)). Zeolite grains which were in equilibrium with the air humidity were applied. The main characteristics of the secondary pore structure of zeolite grains are listed in Table 3. Table 4 contains information on the volume of the secondary pore structure. When applying zeolite grains in practice, it is not the adsorptive power of the unit of mass of the grains which is of vital importance, but the unit of volume of the grain layer. Therefore, the correlation must be established between adsorption properties as well as apparent density of the zeolite granules and the volume of their secondary pore structure. This problem may be solved if composition of zeolite grains and volume of the secondary pores are known from experimental data. The calculated and experimental

Card 3/8

Investigation of the adsorption...

S/062/61/000/009/004/010
B117/B206

characteristic features of A-type zeolite grains are compared with each other in Table 5. The values for the apparent grain density agree well in general. The deviations amount to a maximum of 13%. The calculated and experimental maximum adsorption volumes for water are similar for NaA grains. For most of the CaA grains of Soviet and American origin, the maximum adsorption volumes are below the values calculated from the crystal content. A part of the highly disperse zeolite crystals, i.e. in CaA grains, is obviously excluded from the adsorption process for yet unclarified reasons. The latter are being investigated at present. The comparison of the granulated A-type zeolites synthesized by Soviet scientists with corresponding American specimens showed that with respect to their adsorption properties they are only identical at the surface of secondary pores. This concerns the accessibility of the pore structure of the actual zeolite crystals for the adsorbable molecules, as well as the adsorption of bigger molecules. The zeolite grains investigated show strongly differential volumina of the secondary pore structure. That is the main reason for the fact that the apparent and gravimetric density and thus the adsorption properties of granulated zeolites are different for the units of volume of the grain layers. The authors thank B. A. Lipkind

TITLE: Study of the adsorption properties and secondary porous structure of adsorbents having molecular-sieve action. Report 11. Specific surface of secondary pores of molded synthetic zeolites, type A

SOURCE: AN SSSR. Izvestiya. Seriya khimicheskaya, no. 10, 1965, 1731-1740

TOPIC TAGS: adsorption, zeolite, porosity, molecular sieve

ABSTRACT: ²¹ The analysis of the physical content of various methods of determining the specific surface of the secondary pores of formed zeolites is presented. The specific surface of secondary pores of an equivalent sorbent model with an accepted geometric form of the pores can be calculated from experiments on the depression of mercury and the capillary condensation of benzene. By using a highly sensitive weight adsorption device the specific surfaces, close to actual, of secondary pores of formed Type A zeolites and external surfaces of the zeolite crystals contained in them are determined. The specific surfaces of the secondary pores of the formed zeolites are determined mainly by the porous structure of additives of the binding substances. The specific surfaces of the secondary pores for equivalent porous sor-

3

bent models as a rule are considerably greater than the actual specific surfaces of the secondary pores of real formed zeolites. Hence methods of depression of mercury and capillary condensation of vapors cannot serve as any accurate estimation of the specific surfaces of secondary pores of the formed zeolites. The authors thank B. A. Lipkind, T. G. Plachenov and Ya. V. Mirskiy for making available for research the samples of crystalline and formed zeolites. PERIODICAL: Gidrotekhnicheskoye stroitel'stvo, 1958, Nr 2, pp 36-38 (USSR)

ABSTRACT: The existing bottom water intakes do not ensure a continuous
delivery of sediment-free water. Professor G.A. Dzhimsheli
has designed an improved device in which the simplicity of
open water intakes has been retained. The water is for the
most part freed of bottom sediment before it enters the re-
ceiving gallery. A description of the intake is given.

TITLE: Coalescence of dislocation loops

SOURCE: Fizika tverdogo tela, v. 6, no. 11, 1964, 3383-3391

TOPIC TAGS: dislocation motion, dislocation net formation, dislocation study, radiation damage

ABSTRACT: The article deals specifically with a solution of interstitial atoms and the prismatic dislocation loop produced by such defects in a sample subjected to radiation damage. The authors consider the final stage of dislocation-loop development, when the loop dimensions are sufficiently large and the supersaturation is very low, so that coalescence (growth of large loops by dissolution of smaller ones) is the predominating mechanism. Elastic interaction between loops is assumed negligibly small. Each loop is regarded as

Card 1/2

L 14848-65

ACCESSION NR: AP4048418

growing in an unbounded medium having a certain finite concentration at infinity. By determining the rate of growth of a round prismatic dislocation loop it is shown that for a given concentration of interstitial atoms there exists a critical loop radius, beyond which the loop does not change size. An asymptotic distribution function is obtained for the loop dimensions, and the asymptotic values of the numbers and average dimensions of the loops are determined. "In conclusion, we thank I. M. Lifshitz for valuable advice and discussions." Orig. art. has: 2 figures and 30 formulas.

TITLE: Distribution of charge near a prismatic dislocation loop in an ionic crystal

SOURCE: Fizika tverdogo tela, v. 7, no. 2, 1965, 464-469

TOPIC TAGS: charge distribution, dislocation loop development, vacancy concentration

ABSTRACT: The authors determine the distribution of stationary electric charge near a prismatic round dislocation loop in an ionic crystal. The loop may be either the boundary of a remote part of an atomic plane of circular form (type A) or a boundary between an intruded part of an atomic plane (type B). The charge distribution may be due either to the presence of linear tension along the dislocation or to the action of an external stress. In either case, an inhomogeneous vacancy distribution is produced and gives rise to a diffusion development of the dislocation loop. The direction of this diffusion is determined from the ratio

Card 1/2

L 38539-65

ACCESSION NR: AP5005283

of the equilibrium concentration of the vacancies near the dislocation and the effective "average supersaturation" of the volume. It is shown that in addition to the electric double layer, the volume distribution of the vacancies in the stationary mode, near a dislocation line of non-zero curvature (or subjected to the action of a definite external force), is characterized by a definite total concentration of vacancies near the dislocation core, and the neutralization of the dislocation as a whole is due to formation of charges of opposite sign on other defects. The diffusion flux of vacancies through the surface surrounding the nucleus of the dislocation leads to a change in the dimensions of the prismatic dislocation. These results are new compared with those obtained by Eshelby et al (Phil. Mag. v. 3, 25, 75, 1958). Orig. art. has: 31 formulas.

TITLE: Coalescence of dislocation loops in the nonstationary mode

SOURCE: Fizika tverdogo tela, v. 7, no. 3, 1965, 904-911

TOPIC TAGS: dislocation loop, dislocation motion, vacancy source, interstitial atom source, distribution function

ABSTRACT: This is a continuation of earlier work (FIT v. 6, 3383, 1964), devoted to the coalescence of dislocation loops in the absence of volume sources of vacancies or interstitial atoms. The present article deals with conditions when volume sources of interstitials and vacancies are present, such as is the case under the influence of radiation. The nonstationary mode can arise, for example; if a supersaturated solution of inert gases is produced in the irradiated solid, when the pores filled with gas serve as traps for vacancies, so that the number of interstitial atoms remains uncompensated. The behavior of an ensemble of prismatic dislocation loops in the presence of volume sources is considered under the assumption

TITLE: Contribution to the theory of coalescence of pores with a gas

SOURCE: Fizika tverdogo tela, v. 7, no. 6, 1965, 1605-1611

TOPIC TAGS: porosity, solubility, crystal lattice vacancy

ABSTRACT: This is a continuation of the authors' studies of the coalescence of pores (with I. M. Lifshits, Phys. Chem. Sol. v. 19, 35, 1961 and earlier papers), which arises in the neutron bombardment of fissionable material under certain conditions, when a supersaturated solution of inert gas is produced. The present paper deals with two limiting ratios of the characteristic time of variation of the pore dimension (τ_p) and of the characteristic time of variation of the amount of gas in the pore (τ_0), namely $\tau_p/\tau_0 \ll 1$ and $\tau_p/\tau_0 \gg 1$. The equations for the variation of the radius of the pore containing the gas are set up, and asymptotic solutions are obtained for these equations in the two limiting cases. In addition, asymptotic values are obtained for the size distribution of the pores and for the variation of the average pore dimension with time. The conditions under which each of the limiting cases is realized are discussed from the point of view of the solubilities of the gas and of the vacancies in the host lattice structure. "We thank

TITLE: Influence of coalescence of dislocation loops on the internal friction of hardened metals

SOURCE: Fizika tverdogo tela, v. 7, no. 6, 1965, 1832-1836

TOPIC TAGS: crystal dislocation phenomenon, metal hardening, internal friction

ABSTRACT: The author presents an analysis of the influence of prismatic dislocation loops on the internal friction of hardened crystals. The analysis is based on the assumption that the dislocation loops are purely of the edge (prismatic) type and are circular in form, and that the external stresses can cause the loop to glide only in its own cylindrical glide surface. The characteristic time of the change in the dimension of dislocation loops during the coalescence process is large compared with the period of application of the alternating stress. The dislocation vibrates in the periodic stress field like a stretched string, and the dislocation linear tension force component normal to the glide surface does not change the dissipative force. The time and frequency dependence of the internal friction are determined by solving the differential equation for the oscillating dislocation.

Card 1/2

I. 2518-66

ACCESSION NR: AP5014588

2

It is shown that under coalescence conditions the internal friction of quenched crystals should initially increase with time like $t^{1/2}$, then like $t^{3/2}$, and finally like $t^{-1/2}$. During the first stage the internal friction is independent of the frequency, during the second it is proportional to the frequency, and during the final stage it is inversely proportional to the frequency. TITLE: Diffusion and dislocation mechanism of crystal flow

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 50, no. 4, 1966, 958-970

TOPIC TAGS: crystal dislocation, atom, flow velocity, diffusion mechanism

ABSTRACT: Diffusion mechanism has been analyzed for a crystal flow in which the sources and sinks of point defects (vacancies and interstitial atoms) are prismatic dislocation loops within the crystal grain. A uniaxial external load creates conditions leading to the appearance of diffusion flows which transport the substance from one dislocation loop to another. It was shown that the flows may produce a stationary state in the crystal which is characterized by a constant rate of plastic deformation. If the number of creation centers of the dislocation loops is not very large, the rate of flow of the material should be proportional to the cross section area of the crystal grain and to the volume density of the creation centers. Under certain conditions, the flow velocity increases linearly with the growth of the

Card 1/2

L 36390-66

7.807 kg/cm³ for $p_{sp} = 4 \text{ kg/mm}^2$ to 7.868 kg/cm³ for $p_{sp} = 20 \text{ kg/mm}^2$. Thus, at low pressures, e.g. when $p_{sp} = 4 \text{ kg/mm}^2$ the steel's density is lower (7.807 kg/cm³) than the density of the steel crystallizing while not under pressure (7.824 kg/cm³). The reason is that in the case of crystallization without pressure the shrinkage defects are chiefly represented by a concentrated shrinkage cavity, whereas in the presence of a low pressure exerted by the punch against the metal, there forms a strongly developed shrinkage porosity. The cooling conditions of the ingot also affect the density: if the molten steel is poured into a pressure-die that has a temperature of 20°C, the density of the castings is smaller than that of the castings produced with pressure-dies heated to 200-280°C. Clearly, the lower the cooling rate of the casting in the pressure-die is (i. e. the higher the temperature of the pressure-die is), the higher the density of the casting is. For 15Kh1MIFL steel the optimal conditions of pressure-die casting are: $p_{sp} = 20 \text{ kg/mm}^2$, pressure-die temperature 200-280°C, and pouring temperature (temperature of pouring into pressure-die) 1540-1560°C; the ingots thus obtained display mechanical properties superior to those of the same steel when cast by ordinary techniques, because such pressure-die casting eliminates shrinkage porosity and gas porosity and provides the premises for the so-called "weldability" of grains, i. e. for a state in which the grain boundaries cease to be the weak link and are not inferior in strength to the grain body itself.

Thus, when subjected to tensile tests at 660°C under a load of 22 kg/mm³, specimens of pressure-die-cast 15Kh1M1FL steel withstood fracture for an average of 286 hr compared with 204 hr for specimens of the same steel cast by ordinary techniques. Orig. art. has: 5 figures.

AUTHORS: Rus'yanova, N. D., Kruglov, B. I., Sarancha, Ye. T., Ivanov, V. P., Orestova, V. A., Nikolayeva, N. A., Zel'tser, Ye. Yu., Nessonova, G. D., Turkovskaya, D. V., Boltunova, N. I.

TITLE: News in Brief

PERIODICAL: Zavodskaya laboratoriya, 1959, Vol 25, Nr 9, p 1069 (USSR)

ABSTRACT: N. D. Rus'yanova, Ural'skiy politekhnicheskiy institut (Urals Polytechnic Institute) recommends a polarographic method for the determination of acridine in the analysis of the matrix of anthracite resin. The method is based upon a relationship between the concentration of acridine and the height of the polarogram-wave, the half-wave potential of which lies at 0.79 v. The analysis was carried out on a polarograph of the construction UFAN with a mirror galvanometer M-21. The relative maximum error is given with \pm 3.5% and an analysis time of 10-15 minutes. B. I. Kruglov, Ye. T. Sarancha, and V. P. Ivanov, TsZL Lisichanskogo khimkombinat (Central Works Laboratory of the Lisichansk khimkombinat) describe a method for the radiometric determination of potassium (Ref 1) in a catalyst for the isobutanol synthesis. The investigations were carried out in a B-2 apparatus with a counter tube AS-2.

News in Brief

SOV/32-25-9-13/53

V. A. Orestova, N. A. Nikolayeva, Institut vysokomolekulyarnykh soyedineniy Akademii nauk SSSR (Institute of High-molecular Compounds of the Academy of Sciences, USSR) suggest a rapid method for the determination of sulphur in cation-exchange resins. It consists, in principle, in that the fine pulverized sample is burned in oxygen beside a platinum catalyst, and that combustion products are captured in a neutral hydrogen peroxide solution. The resulting sulphuric acid is titrated in the latter with a 0.01n NaOH solution.

Ye. Yu. Zel'tser, Nauchno-issledovatel'skiy institut elektro-promyshlennosti (Scientific Research Institute of the Electrical Industry) describes a volumetric-complexometric method for the determination of nickel in alloys which are used for the production of permanent magnets on the basis of Fe-Ni-Al-Co-Cu. Ni is separated from the accompanying elements by a 1%-ammoniacal dimethyl glyoxim solution, Co being first transferred into the trivalent form and then titrated with Trilon B.

PROPERTIES AND PROPERTIES INDEX

72

The effect of "paratone" on the viscosity and the viscosity indexes of aviation and automobile lubricating oils. K. K. Papok and I. I. Saranchuk. *Nefteprom Khor.* 1938, No. 3, 51-6. An increase in the "paratone" content in automobile and aviation lubricating oils increases their viscosity at all temps. It also increases the viscosity-temp. index while leaving other physical-chemical const. unchanged. The increase of the viscosity-temp. index depends exclusively upon the "paratone" content and the initial viscosity index of the oil. A 10% addn. of "paratone" increases the viscosity index by 20-3 units in aviation and 40-50 units in automobile lubricating oils; this permits prepn. of aviation oils with a viscosity index of over 100 and automobile lubricating oils with a viscosity index in excess of 60. The expts. are described and results are tabulated. A. A. Bochtlingk

PROCESSED AND PREPARED BY UNIT

Effect of refining on the thermal stability of Emba aviation oils. K. K. Papok and L. I. Saranchuk. *Neftekhim. Khim.* 24, No. 9/10, 51-8(1985). The thermal stability of variously refined residual lubricating oils from Emba crude oil was tested in an app. (illustrated) wherein a thin layer of the oil confined within a metal ring placed on a heated metal plate is subjected to the action of atm. O₂ to form a varnishlike film. The time in min. necessary to form a film capable of resisting a load of 1 kg. applied to the ring is a measure of the stability. The longer the time, the better the stability. Clay treatment of the oil after refining with H₂SO₄ sharply decreases its thermal stability regardless of the type of treatment preceding the acid treatment (alkali treatment, oxidation, or extn. with nitrobenzene). With increase in percentage of the clay used, the stability decreases to a min. at 20-25% of clay and remains unchanged thereafter. Clay treatment has no adverse effect on stability if it follows directly after extn. with nitrobenzene. In any sequence of the different treatments, the best results with respect to stability are always obtained when the acid treatment is last and is followed by neutralization with alkali. This is due presumably to formation of inhibitors during the acid treatment.

Title : Method of express spectral analysis, its advantages and results of
introducing into industry

Periodical : Izv. AN SSSR. Ser. fiz. 18/2, page 271, Mar-Apr 1954

Abstract : The results obtained by industry in applying the I. S. Fishman method
of controlled standards to the analysis of Al-alloys, high-alloyed
steel, cast iron and Ni are mentioned briefly. The application of the
objective express spectral analysis method in industry is highly
recommended by the authors of this report. One USSR reference (1950).

TITLE: Gas turbine installations with piston-type gas generators
[outside the USSR]. (Gazoturbinnye ustanovki s porshnev-
ymi generatorami gaza)

PERIODICAL: "Energomashinostroyeniye" (Power Machinery Construction),
1957, Vol.3, No.8, pp. 36-38 (U.S.S.R.)

ABSTRACT: Piston type gas generators are classified into two
types; free piston gas generators as made by SIGMA and those
with a crank as made by Gotaverken. The SIGMA gas generator
type GS-4, is described and illustrated in Fig.1. The
engines that have been built in France are briefly mentioned.
The Gotaverken locomotive equipment is then described. Mention
is made of proposals to modernise the equipment of US Liberty
ships by the installation of gas generators and gas turbines.

TITLE: Improving the smelting technology of carbon-free ferrochrome in arc furnaces

PERIODICAL: Stal', no. 1, 1962, 43

TEXT: A new method for smelting carbon-free ferrochrome in stationary 3,500 kW arc furnaces (with 420-mm diameter electrodes) was tested. The charge consisted of 4,000 kg chrome ore (55% Cr₂O₃), 1,620 kg silicochrome (50% Si) and 3,800 kg lime, (90% CaO). The new method differed from the conventional one in that silicochrome is fed in two batches: one on the furnace bottom (varying in amount), while the second part of silicochrome is added after the charge (chrome ore and lime) is smelted. 450 tests were made with Xp 0000 (Khr 0000) ferrochrome. By adding part of the silicochrome onto the bottom of the furnace, a great amount of the heat released by the heating of silicochrome could be utilized for smelting the charge, whereas when silicochrome was added later to the charge, the heat developed by the burning silicochrome is only wasted on the overheating of the charge already smelted. Optimum results were obtained when about half of

TITLE: Intensification of metallic manganese smelting by blowing inert gases into the bath

PERIODICAL: Stal', no. 1, 1963, 54 - 55

TEXT: It is known that silicomanganese, upon penetrating through the slag layer is not completely cleaned from silicon and that at the bottom a metal layer forms which contains 3 - 5% Si. Based on the experience that during tapping the silicon content of the metal is reduced by 0.3 - 0.6%, tests were carried out to obtain manganese with a low silicon content by vigorous stirring of the bath. For this purpose the smelting metal was blown through by argon or nitrogen gas via a reducer under a pressure of 1.5 - 3.0 atm. through a 1/2" diameter pipe. Stirring was started after the last bath of silicomanganese was fed into the furnace. During stirring the furnace was not switched off. The tube was deslagged and set in the bath as deep as the slag-metal contact surface or a little deeper, into the metal. Depending on the silicon content the blowing was repeated 3 - 5 times.
