The heats of combustion of camphor, azobenzene and hydrazobenzene. W. SWIETOSLAWSKI AND J. BOBINKA. *Roczniki Chem.* 9, 723-30(730 French)(1920). - The heats of combustion of camphor, azobenzene and hydrazobenzene are in cal. per g. in air: 9200.7, 8483.8, 1024.3; in vacuo: 9248.7, 8477.0, 8017.4. The mol. heats of combustion, ν const. (air): 1408.8, 3544.0, 1587.9. ρ const. (air): 1410.8, 1545.8, 1580.1; ρ const. (vacuum): 1400.0, 1544.0, 1587.8. W. A. Roth's opinion of the non-homogeneity of Lemcuit's data is confirmed (*C. A.* 20, 2445). J. K.

Briquetting of coke and semicoke powders with coal as the binder. H. W. SWIATOSLAWSKI, H. ROJIA AND M. CHORAIN. *Przemysl Chem.* 13, 405 72(1936); *CI. C. 11, 23, 2012*. The higher the coking properties of coal the better it acts as a binder. The nature of the semicoke, depending on whether it came from a coking or a non-coking coal, plays a minor but significant part in briquetting. A min. of 30% coal dust is necessary to produce mechanically strong briquets. The temp. to which the mixt. of coal dust with coke or semicoke dust must be heated before pressing varies between 380° and 440°, depending on the coal dust used as the binder. A pressure of 200-300 kg./sq. cm. is sufficient to produce good briquets. A résumé of over 37 patents on briquetting compiled from international sources is given. A. C. Z.

Application of the differential ebullioscope for the study of azeotropic mixtures of ethyl alcohol and water. W. SWIATOSLAWSKI AND I. ZLOTOWSKI. *Rozniki Chem.* 10, 288-292 (1932) (French); *Collection Czechoslov. Chem. Communications* 2, 315-29 (1933).
 A device composed of an ordinary and a differential ebullioscope was made for the study of azeotropism of mixts. of alc. and water. The variation of the boiling temps. with the compn. of the mixt. was examd. within the limits of water concn. of 0 to 7% under varying pressures from 760 to 1800 mm. Hg. Azeotropic concns. and depressions of the mixts. alc.-water were detd. for 6 pressures: 765, 1025, 1270, 1500, 1740 and 1800 mm. Hg. Tables were compiled contg. the differences between the b. ps. of alc. and the mixts. alc.-water for these 6 pressures and tables contg. the differences between the b. ps. of abs. alc. and the mixts. alc.-water permitting the *deta. of traces of water* in anhyd. alc.

205. Rate of Evaporation of Liquids from a Heated Platinum Surface. W. Swietoslowski and S. Bakowski. *Acad. Polonaise Sci. et Lettres. Bull. 4a-6a. pp. 191-194, April-May, 1950. In English.*—Repeating (Mmo.) Blaszkowska-Zakrzewska's work (see preceding Abstract) with a cavity lined with platinum, the authors discover a temperature-range of instability over which a liquid drop (e.g., alcohol-ether mixture) may take only 5 sec. or alternatively as long as 10-35 sec. to evaporate. The lower value corresponds to a maximum rate of evaporation and is constant over a wide range of temperature; the upper tends to fall slowly at higher temperatures. Thus over the range 210°-270° C. the spheroidal state may or may not be assumed, a result (peculiar to platinum) which the authors attribute to surface irregularities. L. V. C.

Physicochemical researches on alcoholic mixtures. I. Introduction. Wojciech SWIETOSLAWSKI. *Przemysl Chem.* 14, 337-8 (1930).—Compn. by vol., sp. gr. and acidity of mixts. discussed in succeeding instalments are given. II. The phenomenon of azeotropy in polycomponent mixtures. *Ibid* 339-45.—Azeotropic mixts. of 2 and 3 components are considered theoretically. The component A that produces an azeotropic mixt. with other components B and B₁ is called an azeotropizing agent. The difference between the b. p. of component A and the b. p. of the mixt. producing max. vapor pressure is called the azeotropic lowering of the boiling temp. with respect to the component A (in the case of pos. azeotropy). In a series of binary mixts. of an azeotropizing agent A with B, B₁, B₂, . . . etc. (e. g., hydrocarbons) the concn. of A is greater the smaller the azeotropic lowering of the b. p. In such a series no ternary azeotropic mixt. such as B + B₁ + A is formed, but a series of binary azeotropic mixts. such as A + B, A + B₁, . . . etc. are formed. The losses of liquid, in general, were greater the higher the vapor pressure. VIII. Dependence of the temperature of clouding of the mixtures on the amount of added water. W. SWIETOSLAWSKI, J. PRANNAUBER AND S. BAKOWSKI. *Ibid* 497-501.—Clouding and sepn. into 2 phases of the alcoholic fuel mixts. was studied in the relation of temp. to the amt. of water added within the temp. limits of -25° to +30°. A modified form of Alexeyev app. was used. The mixt. PA became turbid the most easily at -18°. Temps. at which the other mixts. sepd. into 2 phases varied from -22.5° to -75°. IX. Flash points, and burning temperatures of alcoholic fuel mixtures. W. SWIETOSLAWSKI AND B. KARPINSKI. *Ibid* 501-3.—Abel's app. was used.

Measuring small temperature effects. W. SWINTOSLAWSKI. *Chem. Listy* 24, 8-11(1930).—An *adiabatic calorimeter* is described by which small temp. effects are measured when the heat is evolved over a long period. The heat given off in minerals poor in radioactive elements can be measured. It is useful in biology for measuring the heat given off during biological oxidations. It cannot be used for the ordinary run of chemical reactions for the events pass through too rapidly. A modification of an *calloscope* is also described. FRANK MARRAN

Preparation of sulfonic derivatives of naphthoquinonechloroamines and naphthoquinonechlorodilmines. W. SWINTOMLAWSKI, A. PILIŃ AND F. KRACKIEWICZ. *Bull. intern. acad. Polonaise* 1931, NO. 2A, 148-57(1931) - See C. A. 25, 3331. G. G.

Thioquinols. LEONARD A. WARREN AND SAMUEL SMILES. *J. Chem. Soc.* 1931, 1192 G. - This derivs. of 2-C₁₀H₇OH of the general type 1,2-C₁₀H₆(OH)SAr (I) are converted by dil. HNO₃ into quinonitroles (II), 1,1,2-C₁₀H₆(SAr)(NO₂)₂O. Under the action of heat in solvents the II decom., yielding complex mixts.; the chief process involved is usually that of hydrolysis, leading to HNO₃ and the thioquinols (III), 1,1,2-ArS(HO)C₁₀H₆O; these have not been isolated, the disulfides resulting from oxidation of the thiols liberated by fission of the III being obtained instead. Concurrently with hydrolysis, migration of the NO₂ group may occur, but the resulting NO₂ derivs. of I have been obtained in only 3 cases. A third type of decompn. (in presence of alkali) involves the removal of the thioaryl group, leaving 1,2-O₂NC₁₀H₆OH. 2-Naphthyl 1-nitro-2-hydro-1,2-dihydro-1-naphthyl sulfide (II, Ar = 2-C₁₀H₇), m. 110° (decompn.), results from the sulfide (I, Ar = 2-C₁₀H₇) and 10% HNO₃ in AcOH; warming in AcOH at 80° gives (2-C₁₀H₇S); EtOH-NaOH gives 1,2-(O₂NC₁₀H₆)OH. The *p*-tolyl deriv. (II, Ar = *p*-C₆H₄), m. 112° (decompn.); the *o*-nitrophenyl deriv. (II, Ar = *o*-O₂NC₆H₄), m. 105° (decompn.); warm AcOH decomps. this, giving *o*-nitrophenyl 1-nitro-2-hydroxy-1-naphthyl sulfide (IV), yellow, m. 192°. The *p*-nitrophenyl deriv., m. 118° (decompn.); warm AcOH gives the *p*-isomer of IV, yellow, m. 187°. 1-Nitro-2'-hydroxy-2-hydro-1,2-dihydrodi-1-naphthyl sulfide (V), from 2-naphthol 1-sulfide (VI), m. 110° (decompn.); warm AcOH gives dehydro-2-naphthol 1-disulfide. 2'-MeO deriv. of V, m. 105° (decompn.); 1'-AcO deriv., m. 102° (decompn.), prepd. from the Ac deriv. of VI, m. 164°; warm AcOH gives the di-Ac deriv. of 2-naphthol 1-disulfide. Shaking 2-naphthol 1-disulfide with Et₂O and dil. H₂SO₄ in the presence of NaNO₂ gives 1-nitro-2-hydro-2'-hydroxy-1,2-dihydrodi-1-naphthyl disulfide, m. 109° (decompn.); 2 N NaOH gives 1,2-O₂NC₁₀H₆OH. Di-1-nitro-2-hydro-1,2-dihydro-1-naphthyl sulfide, m. 121° (decompn.); warm aq. NaOH gives a mixt. of Na salts. The corresponding disulfide, m. 124-7° (decompn.). 2-Naphthol isosulfide and 1 mol. HNO₃ give 95% of nitrodehydro-2-naphthol 1-sulfide; reaction of HNO₃ with the dehydro sulfide did not yield this nitration product.

2488. Adiabatic Microcalorimeter to Determine Specific Heat of Solids and Liquids. W. Swietoslowski, M. Rybicka and W. Seledkowska. *Acad. Polonaise Sci. et Lettres, Bull. No. 4-5A. pp. 322-335, April-May, 1931. In French.*—Corrections for the heat necessary to heat the contained gas, for loss or gain of heat due to adsorption or vaporisation of water (or other liquid) by or from the walls of the apparatus, and for variation in the surrounding temperature, are deduced for the author's adiabatic calorimeter [see Abstract 389 (1938)], and a modified form described. This consists of the microcalorimeter proper, which is placed in a spherical glass or copper vessel, and the whole in a large receptacle filled with water maintained at constant temperature. The substance is heated electrically at a rate of 0.25-0.45° per hr. For determining specific heats two such calorimeters are used, one of silver or copper of known heat capacity, the other similar and containing the liquid under examination for liquids, but made of the metal concerned for a metal. Determined in this way the specific heat at 17° of aluminium is 0.214, of pyridine 0.400. (See following Abstract.) C. A. S.

2489. Measurement of Heats of Adsorption and Vaporisation with Adiabatic Calorimeter. W. Swiatoslawski and (Miss) E. Bartoszewicz. *Acad. Polonaise Sci. et Lettres, Bull. No. 4-5A, pp. 336-347, April-May, 1931. In French.*—To avoid the effect of variations in the surrounding temperature the galvanometer and commutator are placed in the receptacle filled with water. With this and other modifications (fully described) the adiabatic microcalorimeter (see preceding Abstract) is used for determining heats of adsorption and vaporisation with only a few cgm. of liquid. The heats of vaporisation of H₂O, C₆H₆ and CHCl₃ thus determined are 581, 98.2 and 66.8 cal. ($\pm 0.3\%$); the molecular heats of adsorption on charcoal (prepared by the action of ZnCl₂ on wood) of C₆H₆, EtOH and CCl₄ are 14.4, 15.6, and 15.8 cal/mol. ($\pm 0.6-1.7\%$) respectively, all at 20°.

Preparation of sulfonic derivatives of naphthoquinonechloroimines and naphthoquinonechloroimines. W. ŚWIĘTOBLAWSKI, A. PILIŃ AND P. KRACZKIEWICZ. *Roczniki Chem.* 11, 40-48 in French(1931).—1,2,4-C₉H₆(NH)(OH)SO₃H (I), when chlorinated in an aq. suspension with Cl water or gaseous Cl, yields the corresponding quinonechloroimine. The latter, reduced by gaseous SO₂, regenerates I in 45% yield. Similarly, I in a satd. soln. of AcOK, chlorinated at 0° with gaseous Cl, gives K 2-naphthoquinone-1-chloroimino-4-sulfonate, C₉H₅O₂NCISK. This compd. can be reduced with gaseous SO₂ to I with a 97% yield. K 2-naphthoquinone-1-bromoimino-4-sulfonate is prepd. from a soln. or suspension of I in AcOK by treating with Br water satd. with KCl. K 1-naphthoquinone-2-chloroimino-4-sulfonate (II) is prepd. from 1,2,4-C₉H₆(OH)(NH₂)SO₃H by chlorination with a satd. soln. of Cl in satd. KCl during a very short period at -11°. Recrystd. from H₂O it gives bright yellow crystals (yield 45-55%). The product is not sufficiently pure and contains 12.5% of the corresponding naphthoquinone. K naphthoquinone-1,4-dichloroimino-6-sulfonate, C₉H₅O₂N₂Cl₂SK, is obtained in a similar manner from 1,4,6-C₉H₆(NH)₂SO₃H at 10°. The product is very unstable and cannot be recrystd. It is obtained purer than II, but contains still the corresponding naphthoquinone. J. WIKRZYŁAK

Application of the adiabatic microcalorimeter to the measurement of heats of adsorption and of vaporization. W. SWIATOSLAWSKI AND E. BARTOSIEWICZ. *Roczniki Chem.* 11, 78-89(1931)(80 in French).—A modification of S.'s adiabatic microcalorimeter is described. With this new app. the following values of the heat of vaporization at 20° were found: H₂O 581, C₂H₄ 98.2, CHCl₃ 66.8 cal./g. The values of the heat of adsorption on activated charcoal at 20° are: C₂H₄ 14.42, EtOH 15.59, CCl₄ 15.84 cal./mol. The error in the detn. of the heat of vaporization did not exceed 0.3%; that for the heat of adsorption, 0.8-1.7%.

Application of differential ebullioscopes for the examination of the degree of purity of individual liquid substances. W. SWINOSLAWSKI, J. USAKIEWICZ AND A. ZMACZYŃSKI. *Roczniki Chem.* 11, 704-13 (713 in French)(1931); cf. *C. A.* 26, 2087.—Three types of differential ebullioscopes have been used to study the relative purity of so-called "pure" liquids, viz., one with a rectification column and two with dephlegmators of different types. Differences of the b. p. and the condensation temp. ($t_1 - t_2$) of the substance examd. indicate impurities. Many so-called "pure" substances should be classified as "technically pure." The ebullioscopic control of the purity of liquids is recommended. On the basis of detns. made the following standards of purity ($t_1 - t_2$) for liquid substances are proposed: very pure 0.040, sufficiently pure 0.040, relatively pure 0.200, technically pure 0.20-1.00°; for the very pure liquids a rectification column 1 m. in length is used, for the others a dephlegmator 25-7 cm.

5090. Constant-Boiling Mixtures Applied to Analysis of Impurities in Liquids. W. Szydzowski. *Acad. Polonaise Sci. et Lettres, Bull. No. 1-7A, pp. 74-79, Jan.-July, 1932.*—If a liquid L contains small traces of a dissolved impurity A, the quantity of the latter may be determined by means of boiling-point measurements, provided that a third substance B, also soluble in L, but not in A, can be found, such that a constant boiling mixture of A, B and L exists, and also constant-boiling mixtures of the various pairs. Now if a quantity of the component B is added to the constant-boiling mixture of A and L, the boiling point of the A,B,L mixture is lowered considerably below that of the A,L mixture. In practice, the constant-boiling mixture of B and L is prepared, and A is added a little at a time, the boiling point being observed at each addition. The constant-boiling mixture of B with the liquid under examination is next prepared, and its boiling point immediately shows the quantity of A present. The method attains an accuracy of about 0.003%. An alternative method of experimenting is also described. (See also following Abstract.)

Improvement of the quality of Upper Silesian coke. VI. W. Swietoslowski, B. Roga and M. Chorazy. *Przemysl Chem.* 10, 188-90(1932); cf. *C. A.* 26, 6102.—The results of lab. investigations were checked with full-scale app. With slow warming *i. e.*, at low temp. of coking, coke is obtained in large pieces, with few cracks, but of low crushing strength. With increased rate of heating, which occurs when the oven is heated to a high initial temp., the strength increases, the coke is compact, but flaky and in small pieces. Heating in two steps improves the quality of coke, especially if poor-grade coal is used. The addn. of semicoke to the coal before coking markedly improves the quality of the coke, as shown by its increased mech. strength. Semicoke with fully declined phys. properties must be used. In certain cases the addn. of non-coking coal acts favorably. VII. W. Swietoslowski, M. Chorazy and B. Roga. *Ibid.* 17, 25-33(1933).—The coking process is divided into 3 phases differentiated by the physicochem. changes which take place. Besides the insignificant visual changes which take place in the first phase up to the plastic state profound changes occur in the primitive colloidal nature of coal. In the coking and gas-forming caking coals the developed surface of the non-melting and neutral material which is to be cemented together by the surface tension of the semi-liquid mass and the evolution of gas bubbles. Since the surfaces of the coals are developed to widely varying degrees it is difficult to recognize the phenomena. The condition of cementing the solid particles together by means of the semi-liquid mass is considered by the authors in connection with sand, anthracite, coke, semicoke, etc., of the same fineness. In the third phase of the process the real and apparent sp. gr. of the coal change at different rates depending on the kind of coal. The appreciable quantities of gas which are evolved at 700° can escape only by diffusion and through cracks and fissures produced in the coke.

1937

The possibility of spontaneous emission of neutrons by some nonradioactive elements. W. SWIETOSLAWSKI AND A. DORABIALKA. *Roczniki Chem.* 13, 1-4 (1937). Investigations of thermal effects of some chem. elements show the possibility of spontaneous transformation of nonradioactive elements. Analysis of the table of elements and their isotopes shows that transformations α , β , or β' cannot explain existing forms of isotopes without hypothesis of emission of neutrons. Isotopes undergo disintegration when emitting neutrons and are in a state of "neutronogenic" equil. In light elements a neutron produces the fall of an electron into the nucleus of an atom (N) and forms an atom ($N-1$), which is an unstable isotope and emits a neutron. Pos. results in expts. proving neutronogenic decompn. of nonradioactive elements were obtained for Sc, Yt, La, Ac, Sb, Bi and F.

PROCESSES AND PROPERTIES INDEX

Classification of zeotropic and azeotropic mixtures. W. SWISTOSLAWSKI. Roczniki Chem. 12 125-9 (in French 129)(1933). Mixts. of liquids are classified according to degree of poly. of constituents in each other. Zeotropic mixts. are those that do not show max. or min. pressures of constituent liquids; azeotropic mixts. form max. and min. pressures. Homoeotropic and homoeotropic mixts. are those with a single phase; when 2 or more phases appear the mixts. are called heteroeotropic and heteroeotropic.

A study of the degree of purity of benzene and its dehydration by heteroazeotropic distillation. W. Swietoslawski and J. Usakiewicz. *Roczniki Chem.* 13, 103 (1938) (Fréché 490-500) (1933). Dehydration was accomplished within 0.001%. Heteroazeotropic distn. was performed by using a differential ebullioscope with a dephlegmator. Relative purities of C_6H_6 as shown by d_{40}^{20} are: Merck's (*pro analysi*) 80.08%; triply purified 80.110%; differences between b. p. and condensing points are 0.008° and 0.004°, resp., C_6H_6 forms zeotropic azeot. with thiophene. C. T. Ichniowski

Dehydrated ethanol of high purity. W. Swiatkowski and J. Usakiewicz. *Rozwizki Chem.* 13, 540-517551 in French (1933).—A method for obtaining dehydrated ethanol is described. The ethanol is first dehydrated to within 0.4% with CaO and then rectified by heteroazeotrope distn.—the system being EtOH-H₂O-CS₂. The degree of purity of the 3 samples of ethanol studied was detd. by means of two ebullioscopes with dephlegmators, 2) and 5) cm., resp., and a 14-balls rectifying column. Dehydrated ethanol has 78.320 = 0.001-0.002°.

2547. Microcalorimetry. W. Swietoslowski. *Acad. Polonaise Sci. et Lettres, Bull.* 1-3 A. pp. 61-66. Jan.-Feb., 1934. In French.—The paper describes two improvements, both of which are concerned with the elimination of errors due to defects in the thermoelectric circuit used to ensure equality of temperature of the calorimeter and its surrounding mantle. [See Abstract 2489 (1933).] The first device consists in bringing the calorimeter into actual contact with the mantle from time to time and reading the galvanometer under these conditions, when it is certain that calorimeter and mantle are at the same temperature. The second device is concerned with the detection of parasitic e.m.f.'s in the galvanometer circuit.

Several improvements in the adiabatic microcalorimeter, W. Swietoslowski. *Rozwiazki Chem.* 14, 188-91(1934); cf. *C. A.* 30, 3943. The improvements were introduced to avoid systematic errors occurring from e. m. f. changes arising in the thermocouple. The compartment in which the calorimeter is suspended is so constructed as to contain in its base a conical nest the exact size of the calorimeter. At the beginning of the expt. or as the need arises the calorimeter is lowered by means of a weighted thread into the nest to det. the uniformity in temp. (a zero galvanometric reading). A switch is added to the set-up to permit an external control of the thermocouple if there is no e. m. f. These improvements give good results in detg. thermal changes in the setting of *constant*. 3780. Succinic Acid as Secondary Calorimetric Standard. W. Swietoslowski, M. Wojciechowski and E. Sapiro. *Acad. Polonaise Sci. et Lettres, Bull.* 9-10A, pp. 531-539, Nov.-Dec., 1935. In English.— The universal ebullimeter with several dephlegmators is applied to the determination of the quantity of water in a sample of succinic acid used by Kettler for thermochemical measurements. The amount of water in this sample was found to be only 0.003 %. The influence of the temperature on the degree of decomposition of succinic acid is studied when heated to 80° C. the acid slowly decomposes the amount of water (after 9 hours heating in a closed tube), increasing to 0.004 %. When heated to 130° for 8 hours the water content attains 0.018 %, on heating to 180° C. the substance decomposes and becomes yellowish. [See Abstract 4380 (1934).]

18, 348-9 (in French 348-50) (1935) --- A flow calorimeter suitable for the detn. of such continuous heat processes as the hardening of cement is described. In principle the calorimeter consists of a labyrinth of concentric tubes through which water or other calorimetric liquid circulates from the outside to the middle, to avoid loss of heat. The system evolving heat is placed in the central portion and the temps. of the liquid at the entrance and exit are measured. The effect is calcd. from the temp. difference and the amt. of liquid flowing. M. W.

Purification and determination of the degree of purity of toluene. W. Swietoslowski and E. Ramotowski. *Roczniki Chem.* 19, 422-9(1933).—Toluene, obtained in the "fifth degree of purity" (cf. C. A. 29, 4989F) by (1) distn. through a rectification column of 20 bulbs and arranged for slow distn. and (2) by use of a multiplepaleg-mator, has $d_{20} 0.86606$, $n_D^{20} 1.49613$, and most probable b. p. of $110.612-0.614^\circ$. The changes of b. p. and Δt (difference between b. p. and the condensation temp.) are functions of introduced contaminants; Δt varies with the concn. of the contaminant. Toluene undergoes practically no change in b. p. when contaminated with a mixt. of C_6H_6 and *m*-xylene in the ratio 1:1 by wt. but Δt increases in proportion to the amt. of mixt. introduced; a 0.0024% concn. of the adulterant mixt. in toluene increases Δt by 0.001° .

The determination of small quantities of water in solid organic substances. W. Swietoslowski and S. Miernik. *Bull. intern. acad. polonaise, CHIMIE ET MATH. NAT.* 1935A, 2318. - An improved universal ebullimeter (C. A. 25, 236) with one dephlegmator is described. When an absolutely anhyd. solid, such as PhCO_2H , is added to an azeotropic mixt. of C_2H_5 and EtOH in the ebullimeter the temp. of condensation, t , at the top of the dephlegmator is not affected. However, if there is any H_2O in the solid, t will drop. The procedure is to det. t for the azeotropic mixt., add a known wt. of solid, det. t again, and then add known wts. of H_2O dissolved in C_2H_5 and EtOH , detg. t each time. Δt per mg. H_2O can now be calcd. and from the drop in t when the solid was added the percentage of H_2O in the solid is calcd. By using over 15 g. of solid as little as 0.001% H_2O can be detected. Some results were: com. PhCO_2H , 0.13% H_2O ; PhCO_2H , Merck, for calorimetry, 0.016%; same, dried over P_2O_5 , 0.001%; same, heated to b. p. *in vacuo*, 0.002%; com. salicylic acid, 0.050%. Ebulliometric measurements of the moisture content in standard benzoic acid. W. Swietoslowski, M. Wojciechowski and S. Miernik. *Bull. intern. acad. polonaise. Classe sci. math. nat.* 1935A, 59-64; cf. preceding abstract. — A somewhat more complicated app. was used in this case than in the preceding. The ebullimeter had 2 dephlegmators. A sample of standard benzoic acid (sample 48-a, prepd. by the Bureau of Standards at Washington) was found to contain 0.0047 = 0.0008% H₂O. A pellet of PhC₆H₅ contg. 0.002% H₂O was placed in satd. H₂O vapor at 25° for 3 hrs., after which it was found to contain 0.012% H₂O. Therefore, the error in calorimetric detns. caused by the absorption of H₂O on the PhC₆H₅ pellet while the bomb is being prepd. (15-30 min.) is not over 0.1 cal. and may be neglected.

***On the Thermal Effects Which Appear During the Phenomenon of Ageing Aluminium Alloys.** W. Swiętosławski and J. Czocharński (*Wielomotni Instytut Metalurgji i Metaloznawstwa (Warszawa)*, 1936, 3, (2), 59-67).—[In Polish, with German summary.] It has long been supposed that heat effects occur during certain transformations which take place during the recrystallization or ageing of light alloys; at high temperatures such effects have already been observed and by the aid of a specially constructed micro-calorimeter similar effects have now been detected during natural ageing at room temperature. The experiments were made on a 580 grm. block of an alloy of aluminium with copper 2.2, iron 0.66, manganese 0.33, silicon 0.54, and magnesium 0.63% after quenching from 510° C. in cold water. After storage for 22 hrs. at room temperature a rapid evolution of heat occurred which gradually decreased with lapse of time but did not entirely cease until 11 days had elapsed; the total heat evolution between the 22nd and 260th hour was 273.3 grm.-cal. equivalent to 0.4712 grm.-cal./grm. of alloy.—A. 2716. Critical Temperatures of Individual Liquids and their Mixtures. W. Angielski and S. Pioncech. *Acad. Polonae Sci. et Lett. Bull.* 1-2A. pp. 72-80. Jan.-Feb., 1937. In English.— A comparative method of measuring critical temperatures of liquid individual substances and mixtures is described. An apparatus suitable for simultaneous measurements of critical temperatures of several substances is described. A series of mixtures composed of CS₂ and acetone is examined by this method and the most probable composition of the azeotrope (72.1 % of acetone) at critical conditions is reported. It is shown that under these conditions the lowering of critical temperature is 3.3° C., when compared with that of acetone. When the critical temperature of acetone as a reference liquid is taken as 237.5° C., the critical temperature of the azeotropic mixture of CS₂ and acetone is equal to 234.2° C. Auzmoss.

Characterization of coals by agglutination index curves of binary mixtures. W. Swietoslowski, *Tech. Acad. Sci., Poland* 1937; *Ind* 16, 2017 (1937).--S. proposes to classify caking, feebly caking and noncaking gas coals by comparison of the curves of the agglutination indexes of binary mixts. of: (1) coals and coke or anthracite; (2) coals, of which one is a coking standard; (3) coals and pitch. The agglutination indexes are detd. by measuring the strength of crucible cokes in a lab. drum (Roga's test method). The coking quality of a sample is obtained by comparing the index curve of one of the binary mixts. with that for a coal typical of the field being studied. Practical use of the method may be made in com. plants in the selection of optimum blends. D. A. Reynolds

Calorimetric studies of thermal transformations of nitrocellulose powders. W. Swietoslawski, T. Urbanaki, H. Calus and M. Rosinski. *Roczniki Chem.* 17, 444-53 (in English 452-3) (1937).—A calorimeter devised for measuring very small heat effects evolved in processes of long duration was used. Old nitrocellulose powder after previous heating to 75° showed a heat effect, which slowly disappeared; after a second heating to 75° the process of decompn. proceeded with increasing velocity. Freshly prepd. gun powder showed a very small heat effect, which disappeared after some time; a second exposure to the air caused its reappearance. Further contact with air or even with oxygen caused the heat effect to disappear.

21

Agglutinating ability of coal or resin in two- and three-component systems containing other coals or neutral diluting media. W. Swietoslowski and G. Hantke. *Przemysl Chemiczny* 21, 108-10 (1977). Use of the tumbling method of Rings (cf. C. A. 26, 4440) for evaluating the strength of samples of coke prepd. by the crucible method a series of two- and three-component mixts. was investigated in which agglutinating coal or resin was the plastic and binding material, and anthracite, coke or non-agglutinating gas coals were the diluents. In all cases the relationship between the agglutinating value of the mixt. and the concn. of the binding materials was detd. Generally with the greater concns. of agglutinating coal pos. deviations from the mech. strength of the mixt. calcd. on the basis of the additive principle appeared in both the two- and the three-component mixts. Neg. deviations from such values appeared when the proportions of diluents were very great, and especially when the mixt. consisted of very slightly agglutinating coal with coke or anthracite. The addn. of resin to agglutinating coals acted adversely on the strength of coke, but its addn. to slightly agglutinating coals resulted in a gain in strength. While the results do not necessarily reflect the results which would be obtained if the given mixt. were put into a coke oven they nevertheless give an indication of the method of choosing the components whose properties in a mixt. do not obey the additive law. A. C. Zschlin

30446 (in French).—The phenomena called critical take place within a relatively wide interval of temp. and pressure. The temp. at which the vapor (under a pressure such that mist no longer appears when it is passed) is transformed into liquid without formation of mist is that which corresponds with the crit. temp. An app. is described. It consists of capillary tubing of sufficiently stout walls to withstand the pressures developed bent into the form of an oval; after it is filled to one-third of its vol. and the air above the liquid is displaced, the tube is sealed off. One side is heated electrically (the other condensing the vapor) and the change in the meniscus can be observed until the meniscus disappears completely and a mist develops, and finally even this disappears. This is the crit. temp. The temps. are measured by means of a thermocouple placed in the interior of the non-heated arm. The crit. pressure is measured by connecting a N_2 tank by means of a glass spiral which is entirely filled with the liquid under examn. On heating the crit.-temp. tube up to the crit. temp. the vapor liquefies in the cooling arm without formation of mist. On successively decreasing the pressure a value of the pressure is reached at which there is formation of mist, which corresponds to a dispersion of liquid in the vapor. On further diminution of the pressure the mist becomes more dense and finally is quite white, opalescence disappears and at a still lower temp. the fog disappears completely. The phenomenon may also be run in the opposite direction by gradually increasing pressure and it is found that the appearance and the disappearance of the mist occur within the same pressure limits. Louis Waldman

Phase rule and the action of gravity. W. Swietoslawski (Inst. Technol., Warsaw, Poland). *J. Chem. Education* 24, 606-8(1947).—In no system contg. liquids or solids is it possible for the pressure to be everywhere the same. This will lead to the disappearance of the less dense condensed phase if solid, liquid, and vapor are held isothermally at the triple point and layering of the phases with change in temp. if they are raised at the triple point and protected adiabatically. John Howe Pratt

Distillation and crystallization as completing methods of purification. W. Swietoslawski. *Przemysl Chem.* 26, 33-6(1947); cf. *C.A.* 24, 2036; 39, 2092; 3146; 40, 195. The difficulties of azeotropic distn. of benzene and naphthalene-contg. mixts. are discussed. A series of curves is given representing the isobars of azeotropic mixts. of component A with components B, B₁, B₂, ... B_{n-1}, B_n, B_{n+1}. Azeotropic distn., however, even with the most efficient columns, will not yield completely pure aromatics. It is suggested that crystn. and app. for it be perfected and utilized with azeotropic distn. J. Skarbek

534. Dilatometric cryometer. W. Swietoslawska. (*Bull. Int. Acad. Polon. Sci.*, 1948, No. 7-10a, 113-128).—General modified forms of a dilatometric cryometer are described which enable changes in vol. (and thus relative amounts of solid and liquid) and in temp. to be followed during partial or complete freezing or melting of a substance. The cryometer can also be used for determining the purity of substances by accurate f.p. determinations. Samples of impure benzene (0-00%, 0-08, and 0-16% of impurity) are examined and m.-p. differences compared with those for 100% pure benzene by calculation. R. A. CRESSWELL.

The quaternary azeotrope *n*-heptane-benzene-ethanol-water. I. W. Świątosławski and K. Zieborak (Central Inst. Ind. Chem. Research, Warsaw). *Bull. intern. acad. polon. sci., Classe sci. math., et nat. Ser. A*, 1950, 9-12 (in English).—The quaternary azeotrope, $C_7H_{16}(I)-C_6H_6(II)-EtOH(III)-H_2O(IV)$, b. 64.79°, contained 62.4 I, 12.1 II, 18.7 III, and 6.8 wt.-% IV and consisted of 2 phases: the lower, $d_4^{20} 0.8772$, $n_D^{20} 1.3789$, was 17.2 vol.-% or 17.85 wt.-% at 20° of the total and contained 11.8 I, 0.9 II, 54.4 III, and 32.9 wt.-% IV; the upper, $d_4^{20} 0.8385$, $n_D^{20} 1.4640$, contained 73.5 I, 14.5 II, 11.0 III, and 1.0 wt.-% IV. The quaternary azeotrope was detd. by filling a differential ebullimeter with the lower-boiling ternary azeotrope (I-III-IV) and adding small amts. of the higher-boiling ternary azeotrope (II-III-IV), detg. the boiling and condensation temp., and plotting against the compn. of the mixt. The quaternary azeotrope was also prepd. by distn. II. The quaternary azeotrope benzene-ethanol-water-isooctane. *Ibid.* 13-14.—The quaternary azeotrope, I-isooctane (V)-III-IV, b. 64.69°, contained 61.4 I, 14.1 V, 17.7 III, and 6.7 wt.-% IV and consisted of 2 phases: the lower, $d_4^{20} 0.8766$, $n_D^{20} 1.3782$, was 17.0 vol.-% or 17.80 wt.-% of the total at 20° and contained 11.5 I, 1.2 V, 54.6 III, and 32.7 wt.-% IV; the upper, $d_4^{20} 0.8293$, $n_D^{20} 1.4595$, contained 72.2 I, 17.0 V, 9.9 III, and 0.9 wt.-% IV. III. The quaternary azeotrope composed of benzene, ethanol, water, and cyclohexane. K. Zieborak. *Ibid.* 15-18.—The quaternary azeotrope, I-III-IV-cyclohexane (VI), b. 62.19°, contained 54.0 VI, 21.5 I, 17.4 III, and 7.1 wt.-% IV. IV. Tangent and nearly tangent isobars limiting the formation of two-, three-, and four component azeotropes. W. Świątosławski. *Ibid.* 19-26.—By use of the isobar curves of an azeotropic agent, A, with a series of homologs, $B_0, B_1, B_2, \dots, B_n$ (cf. *Ebullimetric Measurements*, 1945, p. 115 (C.A. 39, 2662^o)),

the azeotropic range is defined as the extreme b.p. limits of the corresponding homologs which form tangent or nearly tangent isobars (i.e., the upper and lower limits of azeotropy). The formation of ternary azeotropes of A and C with a series of homologs, B, B_1, B_2 , etc., or their isomers, depends upon the smaller azeotropic range of A with B 's and C with B 's, although the ternary azeotrope range may be somewhat larger than the smaller binary azeotrope range by virtue of the nearly tangent isobars of the binary system. The formation of quaternary azeotropes is limited by the azeotropic capacity of the binary systems (A with B 's having the smallest range; all 3 agents (A, C, and D) should form azeotropes with each other and with the series of homologs (B, B_1, B_2 , etc.) within a certain range; the quaternary azeotrope range may be somewhat larger than the smallest binary range by virtue of nearly tangent isobars of the binary system. In a similar manner, it is concluded that a 5-component azeotrope might exist, although the probability of such formation is small, and its isolation would be difficult since the azeotropic depression with respect to the low-

over

est-boiling quaternary azeotrope would be small. V. Nearly tangent zeotropes and their influence on the formation of ternary and quaternary azeotropes and zeotropes. W. Świątosławski. *Ibid.* 29-33.—In the distn. of I with a small amt. of hydrocarbons, b. 93-100°, the temp. vs. compn. curve has one section corresponding to the formation of nearly tangent binary azeotropes, a transition point from nearly tangent azeotropes to nearly tangent zeotropes, and a section representing the distn. of the zeotropes. If to the ternary azeotrope, I-III-IV, b. 64-85°, is added gasoline (contg. mostly isomeric heptanes and octanes), b. 93-100°, distn. will yield the quaternary azeotrope and the ternary azeotrope, and a somewhat similar distn. curve is obtained. Thus, there is a similarity between the distn. of binary tangent and nearly tangent azeotropes and zeotropes and the distn. of a complicated polycapnent system. The following rule was deduced: If substance B forms with 1 part of a homologous series nearly tangent azeotropes and with another nearly tangent zeotrope, the addn. of a 3rd or 4th azeotropic component leads to the formation of ternary or quaternary azeotropes, resp., whose boiling-temps. differ slightly from each other. These mixts. of ternary or quaternary azeotropes or zeotropes cannot be sepd. by practical distn. Also in *Roczniki Chem.* 25, 88-113(1951).

SWIETOSLAWSKI, W.
Swietoslawski W.

Swietoslawski W. "On the Classification of Sorbents and Ion-Exchangers."
(W sprawie klasyfikacji sorbentow i jonitow). Przemysl Chemiczny, No. 1, 1950,
pp. 41-43.

The author suggests a classification of sorbents and ion-exchangers into: perfect and imperfect groups. To the first belong all sorbents and ionites with one single function, while the other comports those which, in addition to being sorbents also play the part of ionites and vice versa. A suggestion is made to divide ionites into one-, two-, three-, and multi-function groups. The swelling of ionites interferes to some degree with the proposed grouping. There follows a characterization of the secondary processes occurring on non-ideal sorbents and ion-exchangers. A number of Polish terms are proposed for practical use.

2

Classification of sorbents and ion exchangers. W. Swietoslowski. *Przemysł Chém.* 8, (39), 41-3(1930).
A classification of sorbents and ion exchangers is suggested which divides them into two groups: ideal and nonideal sorbents and ionites (ion exchangers). All sorbents and ionites which are characterized by one function only (i.e., sorbents possess adsorption capacity and ionites the ability of ion exchange) are classified in the first group. On the other hand, the nonideal sorbents comprise those which possess either acidic or basic groups or have them absorbed or adsorbed. In both cases the sorbents take part in the ion-exchange process. The ionites may possess the ability of adsorption or absorption of ions from the soln. and therefore may act as ion exchangers as well as sorbents. It is suggested that the phenomena of swelling of ionites and of some sorbents (assocd. with the absorption of relatively large quantities of H₂O) does not interfere with the proposed classification. If sorption of other ions, in addn. to the solvent takes place, the nonideal nature should be stressed. The term chromatography should be retained, though selective adsorption is a more reasonable term. It is suggested that the ionite is in equil. with the soln. when the compn. of the effluent is the same as that of the influent.

Swięcicki W., Zięborak K. Quaternary Azeotrope Composed of Ethanol-Benzene-Water and Normal Heptane.

„O azotropie czterokładnikowym utworzonym z benzenu, etanolu, wody i n-heptanu”. *Przemysł Chemiczny*. No. 7-8, 1950, pp. 420, 2 tabs.

Quaternary azeotrope composed of ethanol-benzene-water and normal heptane has been obtained. It has been characterized by boiling temperature 64.78°C and by the following percentage weight composition: benzene 62.4, ethanol 18.7, water 6.8 and normal heptane 12.1.

Composition, densities and the refractive indexes of both the lower and the upper phases are given. The percentage volume of the lower phase at 20°C is 17.2, which corresponds to 17.85 percent of the percentage weight.

The existence of the quaternary heteroazeotrope composed of benzene — ethanol — water and isooctane (2,2,4 -- trimethyl-pentane) has been demonstrated. The boiling point of the heteroazeotrope at one atmosphere 64.63°C, and the percentages weight composition are as follows: benzene 61.5%, ethanol 17.7%, water 6.7% and isooctane 14.1%. The densities and the refractive indexes of both the liquids have also been determined.
