TITLE: Nature of the  $\epsilon$  -phase in alloys of Fe - Al - C

SOURCE: Kristallografiya, v. 9, no. 2, 1964, 209-212

TOPIC TAGS: epsilon phase, Fe Al C alloy, x ray structure, metallographic analysis, chemical analysis, carbide, Fe sub 3 AlC, eutectic, austenite

ABSTRACT: The authors have studied the high-carbon  $\epsilon$ -phase of Fe-Al-C alloys by x-ray structure, metallographic, and chemical analyses. This phase was found to be an interstitial phase (carbide) corresponding to the formula  $Fe_3AlC$ . It was found that this carbide, like other carbide phases, forms during crystallization from liquid solutions as a primary phase and in eutectic proportions. It also forms during the breakdown of austenite. The macrohardness of the  $\epsilon$ -phase of slowly cooled alloys ranges from 600 to 750 units of  $H\mu$ . The lattice constant depends on the carbon content in the fashion shown in Fig. 1 on the Enclosure.

"Hydraulic Properties of Electromagnetic Pump Ducts; I"

Riga, Magnitnaya Gidrodinamika. (Magnetohydrodynamics), No. 2, 1966, pp 130-134

TOPIC TAGS: electromagnetic pump, friction coefficient, hydraulic resistance  
Abstract: The flow pattern is studied and the coefficients of hydraulic friction of electromagnetic pump duct models are determined neglecting the effect of the magnetic field. The effect of the shape of the convergent and divergent parts of the electromagnetic pump duct on the coefficient of friction is estimated. The duct model investigated consists of a rectangular section with circular inlet and outlet sections tapering down to the rectangular duct.

Details of the experimental configuration and equipment are given. Results of measurements are presented in a table. Results of the flow pattern study will be presented in a future paper. The studies were carried out at the Hydroelectric and Hydroengineering Laboratory of the Kalinin-Leningrad Polytechnical Institute. Orig. art. has: 5 figures and 1 table. [JPRS: 38,764]

*crystallization, single crystal*

ABSTRACT: Reactions in the liquid phase have been studied in the  
Na<sub>2</sub>O-B<sub>2</sub>O<sub>3</sub>-Nd<sub>2</sub>O<sub>3</sub> and Na<sub>2</sub>O-B<sub>2</sub>O<sub>3</sub>-CeO<sub>2</sub> systems under isothermal and poly-  
thermal conditions to obtain data on solubility of the rare earths in  
sodium borate melts and crystallization of the rare earth element  
borates. These data are required for growing single crystals of rare  
earth element borates and for preparing glasses <sup>is. 84</sup> activated with rare-  
earth element ions. Solubility of Nd<sub>2</sub>O<sub>3</sub> and CeO<sub>2</sub> was determined at

900 and 1000C in the melts containing  $B_2O_3$  and  $Na_2O$  in a ratio of from 2:1 to 17:1. This region of compositions was selected as practically the most important from the viewpoint of glass formation. It was noted that the behavior of  $Nd_2O_3$  and  $CeO_2$  in these melts differed. The solubility of  $Nd_2O_3$  was significantly higher than that of  $CeO_2$  because of the formation of neodymium borates,  $NdBO_3$  and  $Nd(BO_2)_3$ , which crystallize in the 2—3.72 and 3.72—17  $B_2O_3/Na_2O$  range, respectively.  $CeO_2$  apparently does not form any compound and its solubility is only slightly dependent on the composition of melts. The great solubility of  $Nd_2O_3$  in the  $Na_2O-B_2O_3$  melts made it possible to grow  $NdBO_3$  acicular single crystals up to several millimeters in size. Such crystals were grown by slow cooling of the borax melt saturated with  $Nd_2O_3$  at 1000C. Liquidus curves of the  $Na_2B_4O_7-Nd_2O_3$  section and  $Na_2B_4O_7-CeO_2$  section of the phase diagrams were established for both systems studied. The liquidus branch of the  $Na_2B_4O_7-Nd_2O_3$  system in the 690—1000C range, and the branch of the  $Na_2B_4O_7-CeO_2$  system in the 740—1100C range corresponded to  $NdBO_3$  and  $CeO_2$  crystallization, both without any polymorphic conversion. Transition points on the liquidus curves at 910C for  $Na_2B_4O_7-Nd_2O_3$  and 930C for  $Na_2B_4O_7-CeO_2$  systems were attributed to some structural changes in the polymeric  $Na_2B_4O_7$  melt.

**The stability of standard arsenious acid solutions. IV. TAMANARY. *Ukrainskii Khim. Zhurnal* 5, Sci. Pt., 217-20(1930).--(1) Standardized arsenious acid loses the strength of its titer through oxidation to arsenic acid. The oxidation rate is directly proportional to the alk. of the soln: A 0.1 N soln. of  $As_2O_3$  in 1 N NaOH suffers a daily loss in titer equaling approx. 0.176% of  $As_2O_3$ . (2) Weakly alk. solns. ( $pH = 7-9$ ) remain unchanged for 1.5 years. (3)  $NaHCO_3$  free from  $Na_2CO_3$  is most suitable and can be prepd. by passing  $CO_2$  through the soln. (4) Solns. of  $As_2O_3$  prepd. from the pure chem. remain sterile and do not form  $AsH_3$ .**

**Rapid Determination of Tin, Copper, and Antimony in Babbitt Metal.** I. V. Tatarsky (Zurnal Prikladnoi Khimii (J. Applied Chem.), 1934, 7, 223-228; 7. 15c., 1935, 88, 2474, and (abstract) *Chem. et Ind.*, 1934, 82, 545-546). [In Russian.] Digest 1 gm. of the alloy with 35 c.c. of concentrated HCl and a little KClO<sub>4</sub>. Make up to exactly 100 c.c. and use 20 c.c. for the determination of Cu. Shake with Bi-Hg at about 50° C. until all the Cu<sup>2+</sup> is reduced to Cu<sup>0</sup> in an atmosphere of CO<sub>2</sub>. Add a crystal of KBrO<sub>3</sub>, and as soon as the colour is gone filter rapidly and titrate with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> to an end point with diphenylamine. In another aliquot determine Sn + Cu similarly. In this case heat with Bi-Hg for 30 minutes at 60°-80° C. To determine Sb, digest 0.5 gm. of alloy in 15 c.c. of concentrated H<sub>2</sub>SO<sub>4</sub>, dilute and filter off PbSO<sub>4</sub>. Dilute with water, add 10-15 c.c. of concentrated HCl, boil for 5 minutes, dilute, and titrate hot with KBrO<sub>3</sub> until methyl orange indicator is decolorized. —S. G.

**Method for preparing pure sodium fluoride. I. V. Tananay.** *J. Applied Chem. (U. S. S. R.)* 7, 728-30 (1954). --KF is difficult to prep. in a pure state, because of its hygroscopicity. NaF 99.90-100.11% pure was obtained (yield 55-60% from the raw material) by the method described. Thus 40-45 g. of the com. prepn. was dissolved in 1000 cc. H<sub>2</sub>O, 15-20 g. of dry KCl added and the soln. filtered after settling. The absence of fluosilicates can be detd. by adding to 10 cc. of the clear soln. one drop of 0.1 N NaOH in the presence of phenolphthalein and heating. If fluosilicates are absent the pink color remains after boiling with addn. of 1 drop of NaOH. More KCl must be added otherwise. The soln. is then evapd. to 100 g., the crystals are filtered through a Gooch crucible with suction, washed with H<sub>2</sub>O to disappearance of Cl<sup>-</sup> (with AgNO<sub>3</sub>) and checked for the presence of Na<sub>2</sub>SiF<sub>6</sub> by evapg. a sample with HCl to dryness (followed by heating to incandescence), the wt. of residue being finally recalcd. to NaF. The mother liquor remaining from the filtration and washing can be used in dissolving new portions of NaF. A. A. Bozhilngk

ca

Solubilities of fluorides of alkaline-earth metals in acids. I. Tamanaev and S. Chrelashvili. *J. Gen. Chem.* (U. S. S. R.) **37**, 11 (1966); cf. *C. A.* **29**, 4335. — A comparative relation between the exptl. and calcd. solubilities in acids of difficultly sol. salts was examd. in the example of  $CaF_2$ ,  $SrF_2$ ,  $MgF_2$  and  $BaF_2$  according to the reaction scheme:  $MF_2 + 2H^+ \rightarrow M^{2+} + 2HF$ . The fluorides were shaken with 0.1 and 1 N HCl in parallel flasks for 0-10 days in satn. Addnl. shaking of sep. tests for 10 days gave no increased solubilities. The results of exptl. solubilities agree with the theory (Kolthoff, *Volumetric Analysis*) and can be calcd. in the value of the product of soly. ( $L_p$ ) and  $pH$  of soln. is known (ex. cept for  $BaF_2$ ).  $L_p$  of difficultly sol. compds. can be detd. also from the soly. data. The magnitude  $L_p$  detd. for  $CaF_2$  and  $SrF_2$  agrees with the published data. For  $MgF_2$ ,  $L_p = 5.6 \times 10^{-10}$  and not  $7 \times 10^{-10}$  (Fredenhagen and Wellmann, *C. A.* **27**, 880). (Ches. Blanc)

**Volumetric determination of potassium. I. V. TANAYANV and E. DZHAPARIDZE (Zavod. Lab., 1937, 6, 1079—1083).**—50 ml. of  $n$ -NaOH are added to a solution of 1–2 g. of carnallite in hot  $H_2O$ , the solution is shaken, diluted to 200 ml., and filtered. An aliquot part of the filtrate is made neutral to Me-orange, excess of 0.25%  $Ca_2Fe(CN)_6$  is added, and the solution is evaporated to dryness. 5 ml. of  $H_2O$  and 15 ml. of 5%  $CaCl_2 \cdot 6H_2O$  in 50% EtOH are added, and the ppt. is collected and washed with the same solution. The ppt. is dried, dissolved in dil.  $H_2SO_4$ , and the solution is titrated with 0.1%  $KMnO_4$  (1 ml. = 14.9 mg. K). R. T.

Adsorption of ions of water by precipitates. I. I. TANANAY AND N. I. MIRIANACHVILI (J. Appl. Chem. USSR, 1937, 10, 1921-1930).—A new type of adsorption, termed hydrolytic adsorption, is presented in the pptn. of  $\text{CaF}_2$  on mixing  $\text{NaF}$  and  $\text{CaCl}_2$  in aq. solution, when the latter becomes acid, as a result of adsorption of  $\text{OH}^-$  by the ppt.; a method for the potentiometric titration of  $\text{F}^-$  based on pptn. of  $\text{CaF}_2$  or  $\text{SrF}_2$  in aq.  $\text{EtOH}$ , is described. R. T.

1ST AND 2ND ORDER												PROCESSES AND PROPERTIES INDEX											
<p><b>Adsorption of ions of water by precipitates.</b> II. I. Tumanov and N. I. Mirianashvili. <i>J. Applied Chem.</i> (U.S.S.R.) 10, 2082-7 (in French 2087 (1937)); cf. <i>C. A.</i> 32, 4407. — <math>K_2CrO_4</math> soln. was electrometrically titrated with a soln. of <math>Pb(NO_3)_2</math>. An abnormally low value of <math>p_{SO_4}</math> (dropping to 3.00), was explained by hydrolytic adsorption. The titration data of <math>Pb^{2+} + CrO_4^{2-}</math> system disclosed an absence of the hydrolytic adsorption. This is probably due to a characteristic property of <math>CrO_4^{2-}</math>. Hydrolytic adsorption was absent also in the systems <math>Cu^{2+} + CrO_4^{2-}</math>, <math>Sn^{2+} + CrO_4^{2-}</math>, and <math>Ba^{2+} + CrO_4^{2-}</math>. <math>AgNO_3</math> adsorbs small amounts of <math>OH^-</math> of water. The low value for <math>p_{SO_4}</math> in the quinhydrone titration was tentatively explained as follows: (1) the Pt electrode adsorbs very small amounts of Ag ion (Ag ion to Ag) and the electrode behaves as a Ag electrode; (2) the soln., contg. Cl, Br and I ions, contains also small amounts of free halides which form the oxidation-reduction system, the system varying its potential in relation to the halide-ion concn.; and (3) Ag ion reacts with quinhydrone beyond an equiv. point with the formation of by-products and upsetting certain equilibrium. An attempt to obtain the titration curves by means of the H electrode in the systems contg. Ag failed. Five references. III. The system <math>Ba^{2+} + SO_4^{2-}</math>. <i>Ibid.</i> 2080-84 (in German 2085). A soln. of <math>BaCl_2</math> and <math>Na_2SO_4</math> (in excess) in alk., as is shown by the methyl red or phenolphthalein indicators. The alk. reaction is promoted by heating, replacing <math>Na_2SO_4</math> by <math>K_2SO_4</math>, increasing the <math>BaSO_4</math>, and adding alc. Since no component of the reaction has an alk. reaction, it is probably due to an adsorption of H ion of water by the ppt. in the presence of the excess <math>SO_4^{2-}</math> ion. The types of adsorption curves for the system in the presence and the absence of potential-forming substances are given. The adsorption titration (defined by the fact that, in performing it, the equiv. point is fixed by a max. variation (during the adsorption) in one ion or another designated as an indicator) was used for titrating <math>SO_4^{2-}</math> ion as follows: Neutralize the sample (<math>K_2SO_4</math>) with NaOH until slightly pinkish to phenol red. Add 50% of alc., and titrate with <math>BaCl_2</math>, adding it slowly by drops. The red coloration of the soln. increases with the titration and disappears rather sharply at the equiv. point. Boil the soln. (as a rule the color reappears) and continue the titration until the color disappears again. The end point appears sooner than it should, the error being 3%. Preliminary establishment of the relation between vols. of <math>BaCl_2</math> and <math>K_2SO_4</math>, and use of this empirical titer for the evaluation of the error are recommended. Six references. IV. The system <math>Pb^{2+} + SO_4^{2-}</math>. <i>Ibid.</i> 11, 120-30 (in French 130) (1938). The method previously described was used. In the system <math>Pb^{2+} + SO_4^{2-}</math> the adsorption of H ions of water takes place in the presence of K ion and an excess of <math>SO_4^{2-}</math> ion but not in the presence of Na ion. The probable formation of <math>K_2SO_4 \cdot PbSO_4</math> is shown by the appearance of equiv. point at half of the vol. of <math>Pb(NO_3)_2</math> required by the reaction: <math>Pb^{2+} + SO_4^{2-} = PbSO_4</math>. The results are not satisfactory for the detn. of <math>SO_4^{2-}</math> ion. Seven references. A. A. Podgorny</p>												2

2. *Chemical Analysis*

**\*Some Applications of Coagulation and Peptization in Chemical Analysis. Determination of Zinc.** I. Tapanasy, D. I. Eristavi, Sh. N. Motatskhvili, L. Galdava, and A. Partakhaladze (*Sov. Geol. Indus. Inst.*, 1939, 10, 100, 167-170; *Khim. Referat. Zhur.*, 1941, 6, 76; *C. Abs.*, 1943, 37, 1667). (In Russian.) In the reaction of  $Zn^{++}$ ,  $K^+$ , and  $Fe(CN)_6^{4-}$ , the equivalent point can be determined by observing the moment of peptization or coagulation of the precipitate formed. The method was used for the determination of Zn. The temperature affects the reaction velocity without displacing the equivalent point; the most suitable temperature is 60°-70° C. The ratio of the ions  $K^+$ ,  $Zn^{++}$ , and  $Fe(CN)_6^{4-}$  affects the reaction velocity and the composition of the precipitate; thus, at small concentrations of  $Zn^{++}$  the equivalent point can be displaced slightly. The error, however, is small and for practical purposes has no effect on the determination of Zn. The error decreases with the increase in the titratable Zn. The equivalent point is displaced at high concentrations of K and Na salts. The presence of electrolytes does not in general the sharpness of the end-point. Therefore, in the presence of electrolytes the solution under investigation is saturated with  $K_4Fe(CN)_6$  with the formation of the sol and back-titrated with  $ZnSO_4$ . An acidity of approx. 0.01 N does not interfere with the titration. The effect of a higher acidity can be overcome by the addition of  $NH_4F$ . To determine Zn in an alloy containing 0.1% Zn, dissolve approx. 1 gram of sample in a 250-c.c. measuring flask in a minimum amount of dilute HCl and add water to the mark. Dilute 25 c.c. of the solution to 50 c.c., heat to 60°-70° C., add  $K_4Fe(CN)_6$  solution in 1 c.c. portions until a stable sol is obtained, and back-titrate with  $ZnSO_4$  until the sol coagulates to flakes. The effect of  $H^+$  and  $Al^{+++}$  can be overcome by adding  $NH_4F$  in amounts that no bluish colour is formed. For an alloy containing 0.01% of Zn as determined potentiometrically, the proposed method gives 100% accuracy.

Volumetric determination of copper in alloys containing antimony. I. V. Tapanay and N. S. Litvinenko. *Zavodskaya Lab.* 9, 668-70(1940).—Two methods were developed for detg. Cu and Sb in Al-Sb-Cu alloys. (1) Dissolve 0.2 g. sample by heating in 5 ml. water and 15 ml. concd. H<sub>2</sub>SO<sub>4</sub>, cool, add 50 ml. water and 10 ml. HCl and heat to dissolve the sulfates. Filter, heat to 70° and titrate the Sb<sup>+++</sup> with KBrO<sub>3</sub> in presence of methyl orange until colorless. Neutralize with NH<sub>3</sub> and add enough NH<sub>3</sub> to form the blue Cu complex. If necessary, after cooling decolorize the soln. by adding dropwise HCl, then 5-10 drops in excess, then 2-3 g. NaHS, shake thoroughly, add 2-3 g. KI and titrate with thiosulfate in presence of starch. (2) Dissolve the sample as above and after titrating the Sb add 15 ml. of 20% sulfosalicylic acid and neutralize with NH<sub>3</sub> to form the Cu ammonium complex. The soln. remains clear and has a greenish blue color. Neutralize the excess NH<sub>3</sub> with sulfosalicylic acid and add 5-10 ml. of 20% sulfosalicylic acid at which the soln. becomes pinkish yellow. Add 2-3 g. KI and after 5 min. titrate with thiosulfate in presence of starch.

**Solubility and ice area in the ternary systems NaF-HF-H<sub>2</sub>O and Na<sub>2</sub>O-H<sub>2</sub>F<sub>2</sub>-H<sub>2</sub>O.** I. V. Tananay, *J. Gen. Chem.* (U. S. S. R.) 11, 267-75(1941). The binary system NaF-H<sub>2</sub>O is investigated below 0°; it shows a eutectic at about -3.5° with 1.75 mol. % NaF; above that point the soly. of NaF increases only slightly with rising temp. (2.08 mol. % NaF at 94°). For the ternary system NaF-HF-H<sub>2</sub>O, the 0° soly. isothermal consists of 5 branches, corresponding to the solid phases: NaF, NaF.HF, NaF.2HF, NaF.3HF and NaF.4HF. NaF + NaF.HF co-exist at 1.91 NaF, 0.09 HF in soln.; with increasing HF (solid phase NaF.HF), the NaF content in soln. first drops to about 0.43 mol. % (HF 12.22 mol. %), then increases; at the transition point from NaF.HF to NaF.2HF (61.7 mol. % HF), the soly. of NaF attains 10 mol. % which is several times as great as the soly. in pure H<sub>2</sub>O. In the system KF-HF-H<sub>2</sub>O, the max. soly. of KF was found at the transition from KP to KP.HF. Appearance of NaF.3HF and of NaF.4HF in the solid phase correspond to about 66 and 70 mol. % HF in soln., without marked changes in the concn. of NaF (about 11-9). In the branch of NaF.4HF, a characteristic bend can be noticed, reminiscent of a similar bend in the soly. curve of KP.4HF. The trend of the curve seems to indicate possible existence of NaF.HF complexes with more than 4 HF, but the measurements could not be followed farther (above 81 mol. % HF). The isothermal at 21° (up to 67 mol. % HF) goes as far as NaF.3HF; at 10° (up to 80 mol. % HF), as far as NaF.HF. With rising temp., the NaF branch becomes longer. Unlike the acid fluorides of K, those of Na have no congruent m. p.; they all decomp. into HF and NaF.HF; the latter is stable up to 90°, and decomp. completely at 150°. Isothermals below 0°, corresponding to crystn. of ice, are represented in projection on basis, for the system Na<sub>2</sub>O-H<sub>2</sub>F<sub>2</sub>-H<sub>2</sub>O and temp. -0.5, -1.0, -1.5, -2.0°. Breaks occur at F:Na = 2 and F:Na = 1. Formation of acid fluorides with more than 2 HF does not appear in the ice area diagrams; failure to detect the higher compds. in the region of ice crystn. has a general significance. N. Thon

9. ~~8~~ *U.S. 2/1/50*

**\*Direct Determination of Aluminum in Alloys.** I. V. JAGANAK and S. T. ABIKOV (*Zhur. Priklad. Khimii (J. Applied Chem.)*, 1942, **15**, (1), 61-70; *C. Abs.*, 1943, **37**, 1668).—[In Russian.] A method is described for determining Al in alloys containing Fe, Cr, Ti, Si, Co, Ni, Zn, Mn; it is based on the

formation of cryolite. The cryolite formed may be weighed as such in the presence of Co, Ni, Zn, and Cr. If Mn, Fe, or Ti is present, the precipitate does not correspond to the proper composition, and the Al is preferably weighed as  $Al_2O_3$ . Fe is co-precipitated with cryolite and reprecipitation is necessary. The precipitation of Al is made in the presence of all elements of the alloy. The procedure is as follows: Place the solution in a centrifuge cup, treat with NaF solution, centrifuge, remove the clear solution, treat the precipitate with more of a 0.5% solution of NaF, and again centrifuge. Do this 2-3 times. Wash the precipitate with 80% alcohol, dry at 130° C., and weigh as cryolite. In the presence of interfering elements, after washing the above precipitate with NaF, dissolve it in HCl solution containing  $H_3BO_3$ , transfer it to a Pt dish, and evaporate with  $H_2SO_4$  until fumes appear. Dissolve the residue in dilute HCl, add  $NH_4OH$ , and continue as usual. If the cryolite precipitate is contaminated with Fe or Ti, repeat the NaF treatment after dissolving the first precipitate in HCl +  $H_3BO_3$ .

Solubility relations at 25° in the system NaF-AlF<sub>3</sub>-H<sub>2</sub>O. (The chemical composition of cryolite.) I. V. Tananay and Yu. L. Lel'chuk. *Doklady Akad. Nauk S. S. S. R.* 41, 118-20(1943).—A satd. aq. soln. of AlF<sub>3</sub> (I) was treated with increasing amts. of NaF, shaken for 8-12 hrs. at 25° and both the pptd. solid and the supernatant solns. were analyzed. As the concn. of NaF in the soln. increased from 0.009% to 1.39% the concn. of I in the soln. decreased from 0.381% to less than 0.001%. As long as the concn. of NaF was less than 1.4%, the compn. of the pptd. solid corresponded to 11NaF·4AlF<sub>3</sub> (cf. C. A. 33, 2047); at concns. of NaF greater than 1.4% the solid phase was 3NaF·AlF<sub>3</sub>. Results of analysis of 3 samples of natural cryolite agreed with the formula 11NaF·AlF<sub>3</sub>. This formula was confirmed by identity of the phenomena observed on heating the synthetic and the natural cryolite samples (transition from monoclinic to cubic cryst. form at 500°, m. 1040°). The possibility of analytically detg. Al as 11NaF·4AlF<sub>3</sub> by pptn. with NaF is pointed out (cf. C. A. 33, 9185). J. W. Perry

**Physical-chemical analysis of systems, important in analytical chemistry. Studies of the formation of silicomolybdic acid.** I. V. Tananayev. *Zashchita Lab.* 11, 246-64 (1945).—Light absorption in the aq. system contg.  $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ ,  $H_2SiO_3$ , and  $H_2SO_4$  was studied by means of the photolec. photometer. The results are given in a tri-dimensional diagram. Only 1 chem. compd. ( $Mo:Si = 12$ ) appears to be formed; its compn. was detd. by the yellow color, and by the blue color obtained on reduction of silicomolybdic acid to molybdenum blue. Silicomolybdic acid is formed at small  $H_2SiO_3$  concns.; it increases with increasing acidity to a max. in the region of  $H_2SO_4$  concns. of approx. 0.01 mol./l., then decreases to zero with increasing acidity. With excess  $H_2SiO_3$  is practically complete transformed to silicomolybdic acid at 0.01-0.0225 mol. of  $H_2SO_4$  in the region of max. values of  $Mo/Si$  studied. A small excess of  $Si$  in the soln. facilitates the same complete formation of silicomolybdic acid, as does an excess of  $Mo$ ; a greater excess of  $Si$  decreases sharply the yield of silicomolybdic acid. Nine references.

1ST AND 2ND EDGES

Physicochemical analysis of systems important in analytic chemistry. III. Solubility in the system  $FeF_3-NaF-H_2O$  at 25°. L. V. Tananayev and E. S. Dikhtman. *Zavodskaya Lab.* 11, 783 (1945); cf. *C.A.* 40, 1400. The soly. isotherm of the ternary system  $FeF_3-NaF-H_2O$  at 25° was studied. There are 2 solid phases in the system:  $FeF_3 \cdot 3H_2O$  and  $2FeF_3 \cdot 5NaF$ . The phase  $2FeF_3 \cdot 5NaF$  is so slightly sol. in NaF solv. that it can be used for quant. sepn. of Fe from soln. and for its sepn. from metals whose fluorides are sol. The properties of the double salt were investigated by optical (immersion), thermographic, and x-ray methods. Addn. of small quantities of NaF to aq.  $FeF_3$  soln. (in the presence of solid  $FeF_3 \cdot 3H_2O$ ) first increased considerably the soly. of  $FeF_3 \cdot 3H_2O$  (from 5.60 to 7.32%), indicating the formation of complex ions in the soln. At NaF = 0.15%, the  $FeF_3 \cdot 3H_2O$  salt was transformed into the double salt  $5NaF \cdot 2FeF_3$ . After this, a 2nd branch of the soly. curve appeared which dropped almost vertically, resulting in the sepn. of  $5NaF \cdot 2FeF_3$ . The intensity of this process is indicated by the fact that increasing the concn. of NaF in the soln. from 0.15 to 0.23% decreased the concn. of  $FeF_3$  from 7.32 to 0.012% (610 times). Later the process slows down and the curve becomes asymptotic at NaF = 0.70%. Further increase in the concn. of NaF results in no changes in the system. The double salt is stable to the end of the isotherm. The salt is sol. congruently. The double salt contains no cryst. water. The salt  $2FeF_3 \cdot 5NaF$  is very slightly sol. in  $H_2O$ , insol. in  $H_2O$ , sol. in HCl,  $HNO_3$ , and  $H_2SO_4$ ; it is decompd. by strong bases and to a smaller degree by  $NH_4OH$  with the sepn. of  $Fe(OH)_3$ . Nine references.

**New potentiometric method for determining nickel with potassium ferrocyanide.** I. V. Tanyazsk and M. I. Levina. *Zhur. Anal. Khim.* 1, 200 (1940). For potentiometric titration of Ni,  $K_4Fe(CN)_6$  is most suitable since it gives the clearest equiv. point. The curve is at first irregular and reproducible with difficulty but the end point, which is simply the highest potentiometer reading, is very sharp. The ratio of Ni to  $Fe(CN)_6$  in the ppt. is somewhat higher than the theoretical value, 1.35 instead of 1.31, and therefore the titrating soln. is best standardized against Ni. The undesirable effect of H ions is best removed by an addn. of NaOAc. Since Cu also reacts with  $Fe(CN)_6$ , it is best removed by Pb amalgam which reduces Cu to metal and Pb ppt. as sulfate. The effect of Pt and Pd is similarly removed. The effect of  $Fe^{+++}$  is prevented by forming  $Fe^{2+}$ . Bivalent Fe is first oxidized with  $H_2O_2$ . The effect of Al

is prevented in the same way. To det. Ni in ores, concentrates, alloys, etc., contg. Cu, Fe, Al, Pt, and Pd, dissolve a 1-1.5 g. sample in 1.5 ml.  $HNO_3$  (1:1) adding later 20 ml. of HCl. Transfer to a porcelain dish, add 5 ml. of  $H_2SO_4$ , heat to appearance of fumes, and then for 5-10 min. longer. Cool, add 100-150 ml. of  $H_2O$ , heat to dissolve salts, filter, and wash the insol. residue. Collect the filtrate in a 250-ml. volumetric flask, add 12-13 ml. of  $H_2SO_4$ , and dil. to vol. To 75 ml. of soln., add 150-200 g. of 3-5% Pb amalgam to reduce Cu, Pt, and Pd, shake vigorously, and allow the ppt. to settle (or filter if desired). To 25-30 ml. of the reduced soln. add a slight excess of  $NH_4OH$ , 1-2 drops of  $H_2O_2$ , boil for 2-3 min., acidify with 18 N  $H_2SO_4$  to dissolve ppt., cool, add NaOAc until the soln. turns brownish and 0.5-1 g. more. Add 1-1.5 g. of KI and titrate potentiometrically.

Physicochemical analysis of systems important in analytical chemistry. Solubility of lead sulfate in aqueous solutions of nitrates. I. V. Tsypchenko and I. B. Minatskaya. *Zhur. Anal. Khim.* 1, No. 1, 95-102 (1946); cf. C.A. 41, 1167h. The soly. of  $PbSO_4$  at  $25^\circ$  in aq. solns. of the nitrates of Li, Na, K, Ca, and Al in concns. of 0.0001-1.0 M was studied. Pb was detd. polarographic-ally except in systems contg.  $Al(NO_3)_3$  in which it was detd. iodometrically. The effect of foreign ions on the soly. does not depend solely on the valency of the ions; their chem. properties should be taken into account. Consequently the Debye-Hückel formulae must be modified to take into account the chem. interaction of the ions. The soly. of  $PbSO_4$  and its soly. product is  $M$  solns. of the electrolytes increased from K to Li, i.e., in the direction of decreasing ionic radii or increasing hydrophilic properties, and also with increasing volume (Ca and Al). The same order is observed in colloid chem. (lyotropic series) and in captn. phenomena. Within the range of concns. studied the soly. of  $PbSO_4$  is  $\sqrt{1.68} \times 10^{-4}/10^{-4}$ , where  $A$  is the neg. log of the activity coeff. M. Hirsch.

III AND IHD CRDERS

Physicochemical analysis of systems of analytical significance. V. The system  $FeF_3 \cdot KF \cdot H_2O$ . I. V. Tananay and B. N. Delehan (N. S. Kurnakov Inst. Gen. Inorg. Chem. Acad. Sci. U.S.S.R., Moscow). *Izv. Akad. Nauk S.S.S.R., Otdel. Khim. Nauk* 1946, No. 4, 373-80; cf. *C.A.* 41, 6125c. — At 25°, addn. of smallest amts. of KF (up to 0.5 wt. %) to a soln. of  $FeF_3$  results in some increase of the soly. of the latter, from 5.6% (at  $KF = 0$ ) to 7.0%, indicating formation of complex anions. At 0.5% KF, the solid phase  $2KF \cdot FeF_3 \cdot 11H_2O$  (I) appears; soly. of  $FeF_3$  drops sharply, and, from  $KF$  3% up, not more than 0.002%  $FeF_3$  is found in soln. The solid phase between  $KF$  2.4 and 8.9% corresponds to the compn.  $11 KF \cdot 4FeF_3 \cdot 12H_2O$  (II), analogous to the salt  $11 NaF \cdot 4AlF_3$  (*C.A.* 36, 3542). Above 9% KF, and up to 33.4%, the solid phase is  $3KF \cdot FeF_3 \cdot 3H_2O$  (III). The exact position of the transition  $II \rightleftharpoons III$  could not be detd. Salt I dissolves congruently, 0.018 moles/l. at 25°; the crystals have  $n_D < 1.46$ ,  $n_D = 1.40$ . The debyogram (37 lines measured) is different from for  $FeF_3 \cdot 3H_2O$ , II, and III. Thermography shows 3 effects, elimination of crystn.  $H_2O$  at 105-20°, decompn. into KF and  $FeF_3$  at 680-705°, and melting of both components at 1005°. Solution of II brings about decompn. into I and KF; III, dissolving, goes over first into II, then into I and KF. Debyograms of II are characteristic only of that salt; lines of  $FeF_3 \cdot 3H_2O$  and of I are absent; the debyogram of III is identical with that of II, except for 3 weak addnl. lines in III. Fair-sized orthorhombic crystals could be grown only with II, giving  $n = 1.43$ . Thermograms of II show

dehydration at 120-70°, those of III dehydration 110-50° and decompn. into components at 785-820°. N. T.

A new method for the separation of small quantities of zinc, nickel, cobalt, manganese, cadmium, copper, and titanium from large quantities of iron. I. V. Tarasov, and E. N. Deikman. *Zavodskaya Lab.* 12, 30-7 (1946).-- The new method proposed for the sepn. of small quantities of Zn, Co, Ni, Mn, Cd, Cu, and Ti from large quantities of Fe is based on the formation of double salts:  $5 \text{NaF} \cdot 2 \text{FeF}_3$  or  $2 \text{KF} \cdot \text{FeF}_3 \cdot \text{H}_2\text{O}$  and  $11 \text{KF} \cdot 4 \text{FeF}_3 \cdot 12 \text{H}_2\text{O}$ . The completeness of the sepn. depends on the acidity of the soln. (1-3 ml. of concd. HCl or  $\text{H}_2\text{SO}_4$  in 100 ml. of soln.). The ppt. of the double fluoride of Fe is cryst., has a small vol., and filters well from hot soln. The method is superior to older methods, based on hydrolytic pptn. of Fe. The soln. is diltd. to 100 ml., acidified with HCl or  $\text{H}_2\text{SO}_4$ , heated to boiling, small portions of 20% KF (or solid NaF) are added slowly (the intensively colored, orange soln. decolorizes, owing to the formation of the undissol'd.  $\text{FeF}_3$ , and a white ppt. of the double fluoride is formed). The ppt. can be filtered after several min. with a suitable wash liquid, and the desired element detd. in the filtrate. The optimum acidity in detns. of Zn (relative content 1%) was 0.5-1.0 ml. of HCl in 100 ml. The ppt. absorbs more Zn when the detn. is carried out in the cold. No Ni or Co was formed in the ppt. when proper exptl. conditions were followed. Satisfactory results were obtained in detns. of Ni in the filtrate. Mn was detd. in the filtrate colorimetrically. Addn. of 3 ml. of  $\text{H}_2\text{SO}_4$  reduced considerably the Mn content in the ppt. and it could be sepal. completely from Fe by repptn. with  $\text{H}_2\text{BO}_3$ . The optimum acidity in sepn. of Cd was approx. 0.5 wt. % of HCl. Better results were obtained with NaF than with KF. The sepn. of Cu was most complete with an acidity of approx. 1 ml. of  $\text{H}_2\text{SO}_4$  in 100 ml. of soln. The sepn. with NaF was quant. Sepn. of Ti with KF was more difficult than that of the other elements. With NaF nearly satisfactory results were obtained at an acidity of 3 ml. of  $\text{H}_2\text{SO}_4$  per 100 ml. of soln. A double pptn. of Fe yielded a complete sepn. of Ti. 3 references. W. R. Henn

Determination of nickel and cobalt in iron ores with the separation of iron by sodium fluoride. I. V. Tamaev and V. G. Sil'nichenko (Inst. Gen. Inorg. Chem., Acad. Sci. U.S.S.R.), *Zhurn. Prikl. Khim.*, 12, 140-1 (1949). To about 100 ml. of the acid soln. contg. considerable Fe<sup>+++</sup> and little Ni<sup>++</sup> add NaOH soln. till a faint turbidity persists and dissolve this with a few drops of HCl. To the hot soln. add 20-100 ml. of hot, 4% NaF soln. Allow the resulting ppt. of Na<sub>2</sub>FeF<sub>6</sub> to settle for 8-10 min., filter, and in the filtrate det. Ni with dimethylglyoxime. A similar treatment serves to sep. Co from most of the Fe. In the filtrate from the NaF pptn., Ni plus Co can be detd. by electrolysis of an ammoniacal soln. W. R. H.

PROCESSES AND PROPERTIES INDEX

Volumetric determination of nickel by titration with dimethylglyoxime solution. M. I. Levina and L. A. Yanusovskaya. *Zhuravskaya Lab.* 12, 245-6 (1965). The method proposed is a modification of the Black, Gail, and Kruger method (cf. *C.I.* 30, 5720). The noble metals (Pt, Pd, Ir, and Rh) and Cu are removed by means of Zn or Hg amalgam and Fe is removed by converting Fe<sup>+++</sup> into the insol. double salt 5NaF·2FeF<sub>3</sub> by means of NaF. Shaking the sample H<sub>2</sub>SO<sub>4</sub> soln. with Zn or Pb amalgam reduces Pt<sup>+++</sup>, Pd<sup>+++</sup>, Ir<sup>+++</sup>, Rh<sup>+++</sup>, and Cu<sup>++</sup> to the metallic state when they are absorbed by Hg. If Zn amalgam is used, some Zn dissolves, but it does not interfere with the titration. After removal of the amalgam, add NH<sub>4</sub>OH and 1-2 drops of H<sub>2</sub>O<sub>2</sub> to the soln. contg. only Ni and Fe<sup>++</sup>, heat to boiling, acidify with HCl, add 1 g. of AcONa and 2-3 g. of solid NaF, and titrate the hot soln. with alc. dimethylglyoxime. From time to time transfer 1 drop of the liquid with the ppt. to the indicator paper covered with a piece of filter paper (to prevent the ppt. from coming in contact with the indicator paper). The titration is completed when no pink spot appears on the indicator paper. The titer of dimethylglyoxime is gravimetrically set by a standard soln. of Ni prepd. from metallic Ni or from some Ni salt. The accuracy of the method is approx. 2% (relative). In analyses of slime contg. 5.30% the content found was 5.42%.

**Rapid determination of silicic acid in blast-furnace slags, and of silicon in cast iron with the use of Joiner's glue.**  
 L. V. Tananayev, *Zhuravskaya Lab.* 12, 218 (1946).

To det.  $SiO_2$  in blast-furnace slag, dissolve 0.5 g. of the finely ground slag by heating in a 50-100-ml. beaker with 15-20 ml. of HCl, add 10 ml. of 1% Joiner glue, mix thoroughly for 2-3 min., dil. with hot water to 40-80 ml., mix, filter rapidly in a Buchner funnel (5-7 cm.) under a slightly reduced pressure, transfer the  $SiO_2$  residue to a filter, wash first 3-4 times with hot 1% HCl soln., then 4-5 times with hot water, dry the filter with the ppt. in a porcelain crucible, ignite at 950-1000°, and weigh. To det. Si in cast iron, dissolve 1 g. of the cast iron by heating in a 100-ml. beaker with 20 ml. of  $H_2SO_4$  +  $HNO_3$  (mix 2:1 of  $H_2SO_4$  (d. 1.84) with 5.5:1. of distd. water, cool, and add 1.5 ml. of  $HNO_3$  (d. 1.4)), add 10-15 ml. of hot water and 10 ml. of 1% Joiner's glue, mix thoroughly for 1-2 min., add water to 80 ml., mix, filter rapidly, transfer the ppt. to a filter, wash first 3-4 times with hot 1% HCl soln., then 4-5 times with hot water, wash the ppt., dry in a porcelain crucible, ignite at 950-1000°, and weigh. The time required for the detn. is 30-40 min. The porous ppt. of  $SiO_2$  is easily washed. The ignited silica requires no treatment with HF.      W. R. Henn.

13T41

Complex fluoride compounds of tantalum and columbium. G. S. Savchenko and I. V. Tananay, *J. Appl. Chem. (U.S.S.R.)* 19, 1083-1106 (1957) (in Russian).

- Titration of  $K_2TaF_7$  solns. in dil. HF with NaOH with phenolphthalein, methyl orange, and methyl red as indicators (the last in the presence of  $CaCl_2$ ) consumes, resp., 5-6, 3.5-4.5, 4.4-4.7 mols. NaOH per mol.  $K_2TaF_7$ ; the figure 4.5 mols. NaOH, with methyl red, was adopted. The 25° soly. isotherm of the  $K_2TaF_7$ -HF-H<sub>2</sub>O system shows that the soly. of  $K_2TaF_7$  increases with increasing HF, up to a max. 14.9% at 45.20% HF; at this point, the ratio  $KF:TaF_5$  in soln. rises sharply; the new solid phase, appearing from this point on was shown to be  $KTaF_6$ , by analysis of the product synthesized in 3 ways: (a) Ta was dissolved in HF + HNO<sub>3</sub>, the soln. concd., 70-90% HF added to make the soln. 50-60% in HF, and pptd. with a KHF<sub>2</sub> soln. in an amt. calcd. for  $K_2TaF_7$ ; the ppt. was washed with 50% HF and dried; (b) same method, with double the amt. of KHF<sub>2</sub>; (c) by recrystn. of the first product in 50% HF; the 3 products were identical,  $KTaF_6$ . Below 45% HF, the salt decomposes according to  $2K_2TaF_7 = K_3TaF_7 + TaF_5$ . Above that point, the soly. of  $KTaF_6$  at 25° as a function of HF is congruent and has a shallow min. (15.93%) at about 54% HF.  $K_2CbF_7$  was prepd. by dissolving Cb in HF + HNO<sub>3</sub>, concg., treating with KF, washing the ppt. with alc., and recrystg. from 10% HF; on heating at 110°, the salt evolves HF continuously. Titration of  $K_2CbF_7$  in dil. HF with NaOH (methyl red, in the presence of  $CaCl_2$ ) consumes 5 mols. NaOH per mol.  $CbF_5$ . On account of the spontaneous hydrolysis of  $K_2CbF_7$  into  $K_2CbOP_2 \cdot H_2O$  and HF, the soly. isotherm  $K_2CbF_7$ -HF-H<sub>2</sub>O at 25° was investigated by increasing only the amt. of  $K_2CbF_7$ , without adding HF, until the compn. of the soln. became const. on further addn. of the salt; from then on the HF content was raised by direct addn. of HF. The soly. of the salt first increases with rising HF content, up to a max. at about 7% HF, then falls and passes through a min. at about 26.27% HF; along the rising branch, the solid phase is  $K_2CbOP_2 \cdot H_2O$ ; at the max. solid  $K_2CbOP_2 \cdot H_2O$  and  $K_2CbF_7$  coexist; the latter is the solid phase up to about 40.5% HF, where the ratio  $KF:CbF_5$  in soln. changes abruptly from about a const. 2 to increasing values. The new solid phase is  $KCbF_6$ , synthesized in the same way as  $KTaF_6$ . With HF increasing from 40.5% to 50%, the soly. of  $KCbF_6$  is congruent and falls slowly and uniformly. For the system  $K_2TaF_7$ - $K_2CbF_7$ -HF-H<sub>2</sub>O at 25°, the sum Ta + Cb (as  $Ta_2O_5$  +  $Cb_2O_5$ ) in soln. was detd. as a function of HF, in the presence of both Ta and Cb in the solid phase. The combined soly. rises with increasing HF up to 5.90% at HF 3.75%; solid phase  $K_2CbOP_2 \cdot H_2O$  +  $K_2TaF_7$ ; falls down to a min. of 3.34% at HF 17.10% and then rises again, solid phase  $K_2CbF_7$  +  $K_2TaF_7$ ; the "combined" soly. is somewhat lower than the sum of individual solubilities, owing to mutual salting out; no chem. interaction and no solid soln. are observed. The conditions of stability of double compls.  $nRF_2M_2$  (R = alkali metal, M = Ta, Cb) are represented by a plot of  $n$  ( $n = 1, 2, 3$ ) against increasing HF (to the right of the zero) and increasing RF (to the left of the zero); with increasing HF (decreasing RF),  $n$  falls linearly, the order from left to right being Cs, Rb, K, Na, NH<sub>4</sub>; example,  $2RbF_2TaF_7$  is stable at a lower HF concn. than  $RbF_2TaF_7$ ;  $3NH_4F_2TaF_7$  is stable at a slightly higher HF than  $2RbF_2TaF_7$ ;  $2NH_4F_2TaF_7$  can only exist at considerably higher HF,  $NH_4F_2TaF_7$  only at very high HF. (7) All known (20) double alkali metal fluorotantalates and fluorocolumbates are listed including the new  $KTaF_6$  and  $KCbF_6$ . (8) Soly. data do not promise any better conditions for the sepn. of Ta and Cb than through their  $2KF \cdot MF_2$  salts. N. Thou

Physicochemical analyses of a system important in analytical chemistry. System  $AlF_3 - NaF - H_2O$ . I. V. Tananay and Yu. L. Le'chuk. *Zhur. Anal. Khim.* 2, 99-102 (1947); cf. *C.A.* 43, 8320f. --When NaF is added to sat'd. solns. of  $AlF_3$ , two double salts can be formed. The more stable salt is  $11NaF \cdot 4AlF_3$ . It predominates with low concns. of NaF and the other salt,  $3NaF \cdot AlF_3$ , appears at higher concns. of NaF but in dil. solns. is hydrolyzed into the more stable salt. Considerable data are given to prove that the formula of cryolite is really that of the first salt and not  $Na_2AlF_6$ , as has been assumed. In this form  $Al^{3+}$  can be pptd. from fluoride solns. and sepd. from most other ions in quant. analysis.

**Complex fluorides of tantalum and of columbium. II.**  
 (I. H. Baychenko and I. V. Tananayev, *J. Applied Chem. (U.S.S.R.)* 29, 395-99 (1977) (in Russian); *ibid.* 41, 4733d. (1) The soly. of  $K_2TaF_7$  in  $H_2O$  in the presence of HF at 75° rises increasingly steeply with the amt. of HF; up to 35.5% HF, there is no change in the compn. of the solid phase. Soly. of  $K_2CbF_7$  at 75° is about 3 times higher than at 25°; up to about 5% HF the solid phase is  $K_2CbOF_6 \cdot H_2O$ , beyond that point it is  $K_2CbF_7$ ; at the transition point the soly. is max. (CbF, 23.77, KP 14.38%), then it drops sharply and passes through a min. (CbF, 11.00, KP 0.80%) at about 20% HF; the compn. of the solid phase remains const. up to 33.6% HF. (2) The quaternary systems  $K_2TaF_7(K_2CbF_7)$ -KF-HF- $H_2O$  were investigated at 25° - 0.1° along the sections HF = 1, 2, 5, and 10%, at KP = 1, 2, 5, and 10% in each section, tabulated and plotted in soly. curves of  $K_2TaF_7(K_2CbF_7)$  against KP. The soly. of  $K_2TaF_7$  decreases with increasing KP, fastest at the lowest KP; above 5% KP, the soly. remains practically const.; increasing HF content shifts the soly. curves upwards without change in shape; 1% KP decreases the soly. of  $K_2TaF_7$  to  $1/10$  its value, 2% KP to  $1/100$ , 5% KP, to  $1/1000$ ; possibly, at this concn.,  $K_2TaF_7$  is completely insol., the residual soly. observed belonging to the Cb salt present in the  $K_2TaF_7$ . The corresponding curves for  $K_2CbF_7$  are qualitatively similar to  $K_2TaF_7$ , but quantitatively different: in 1% HF, change of KP from 0 to 10% decreases the soly. of  $K_2CbF_7$  to  $1/100$ , in 2, 3, and 10% HF only to  $1/1000$ ; at low concns. of KP, the fall of soly. is much slower than in the case of  $K_2TaF_7$ ; thus, 1% KP decreases the soly. of  $K_2CbF_7$  to  $1/10$  as compared to  $1/100$  for  $K_2TaF_7$ . Plots of the soly. ratio  $K_2CbF_7/K_2TaF_7$  against KP (at const. HF) have a max. at about 5% KP, at any HF concn. (3) From a weakly acid (HF) mixed soln. of  $TaF_5$  and  $CbF_5$ , addn. of KP up to 2% in soln. will ppt.  $K_2TaF_7$  if it is present at over 0.05%;  $K_2CbF_7$  will not ppt. under these conditions as long as its concn. is less than 3%; if there is more of it,  $K_2TaF_7$  can still be pptd. pure by dilg. the soln.; it can be purified still farther by recrystn. from dil. HF. The  $K_2CbF_7$  obtained by evapn. of the filtrate contains about 1%  $K_2TaF_7$ ; it can be freed from it by a single recrystn. from dil. HF. Practically, it is preferable to carry out the sepn. at 1-2% HF, with the Cb sepg. in the form of  $K_2CbOF_6 \cdot H_2O$ . N. T.

Physicochemical analysis of systems of importance in analytical chemistry. XIII. System  $\text{CoSO}_4 \cdot \text{K}_4\text{Fe}(\text{CN})_6 \cdot \text{H}_2\text{O}$ . L. V. Tarasova and M. I. Levina. *Zhur. Anal. Khim.* 3, 31-40 (1948); cf. C.A. 42, 6267. -Definite vols. of  $\text{CoSO}_4$  and  $\text{K}_4\text{Fe}(\text{CN})_6$  solns., both of known compn., were mixed at 25° and the supernatant liquid was analyzed electrolytically, colorimetrically, or turbidimetrically to det. the compn. of the ppt. Two double salts were found:  $6\text{Co}_2\text{Fe}(\text{CN})_6 \cdot \text{K}_4\text{Fe}(\text{CN})_6$  and  $10\text{Co}_2\text{Fe}(\text{CN})_6 \cdot 3\text{K}_4\text{Fe}(\text{CN})_6$ . The latter is less stable than the former and tends to peptize near its equiv. point. The existence of these 2 salts was confirmed by x-rays. An excess of  $\text{K}_4\text{Fe}(\text{CN})_6$  coagulates the dispersion. The formation of these 2 double salts suggests 2 methods of analysis. In the 1st of these methods, a soln. of  $\text{CoSO}_4$  is titrated with  $\text{K}_4\text{Fe}(\text{CN})_6$  while the extinction is measured; the end point corresponds to the max. extinction. This point occurs at  $\frac{\text{Fe}(\text{CN})_6^{4-}}{\text{Co}^{2+}} = 0.6$  which corresponds to the compn.  $5\text{Co}_2\text{Fe}(\text{CN})_6 \cdot \text{K}_4\text{Fe}(\text{CN})_6$ . This method of analysis is preferred for small concns. of Co. For larger quantities of Co, the unknown soln. is titrated with  $\text{K}_4\text{Fe}(\text{CN})_6$  until the dispersion formed coagulates. The supernatant liquid is filtered off and the excess  $\text{K}_4\text{Fe}(\text{CN})_6$  in it is titrated with  $\text{KMnO}_4$ . The compn. of the ppt. is  $4\text{Co}_2\text{Fe}(\text{CN})_6 \cdot 3\text{K}_4\text{Fe}(\text{CN})_6$ . M. Hosh

**Physicochemical analysis of systems of significance in analytical chemistry. XIV. A study of the system  $K_2PdCl_6-KI-H_2O$  by the light absorption method.** I. V. Tanasaryan. *Zhur. Inst. Khim.* 5, 278-83 (1968); cf. CHEM. ABST., 63, 10611. Four series of solns. were studied with respect to light absorption. In all cases the total vol. was 25 ml. The concn. of  $K_2PdCl_6$  was  $4 \times 10^{-4}$ ,  $8 \times 10^{-4}$ ,  $2 \times 10^{-3}$ , and  $4 \times 10^{-3}$  and kept const. in each series but the concn. of KI was gradually increased. The light absorption values were plotted as log KI concn. vs. extinction. The results show that a peak in the plotted graph occurs when the ratio  $[KI]/[Pd] = 2$  corresponding to the formation of  $PdI_2$ . The second phase as the KI concn. is increased gives a line practically parallel to the axis of the abscissas. A false peak is obtained when KI is about 0.05 M. Finally the ppt. begins to dissolve with the formation of  $PdI_4^{2-}$  and the soln. turns red. These facts can be used for detg. Pd by titration to the max. turbidity. The formation of  $PdI_2$  can be used for a colorimetric detn.

Physicochemical analysis of systems significant in analytical chemistry. IV. The interaction of  $PtCl_4$  and  $KI$  ions in aqueous solutions. I. V. Tammov, *Izvest. Sibirsk. Platiny i Drugikh Blagorod. Metal. Tsit. Obshch. Khim. i Neorg. Khim., Abad. Nauk S.S.S.R.* No. 21, 213-18 (1948).—Sols. of  $KI$  and  $(NH_4)_2PtCl_6$  were combined in a manner such that the  $KI:Pt$  ratio was varied, and the color intensity of the resulting soln. was detd. in a photorec. colorimeter. There were 2 series of solns.: in one of these the  $Pt$  content was const., in the other both the  $Pt$  and the  $KI$  were varied. The exptl. results were used for constructing a space diagram of state. Solns. having a concn. too dense to be measured accurately were diltd. Readings thus obtained were reproducible. Time required to attain equil. varied for different sections of the system. Where homogeneity was preserved, equil. was reached within 24 hrs.; where a ppt. formed, it required 7 or more days. In the series of solns. with a const. content of  $Pt$ , light absorption increased with the quantity of  $KI$  and reached a max. at  $KI:Pt = 4$ . Beyond this  $KI:Pt$  ratio, the absorption dropped until a ratio 6, after which there was a slight rise in absorption and a limiting value was reached. The curve  $KI:Pt$  ratio vs. difference in absorption between consecutively increasing  $KI:Pt$  ratios revealed 2 steps at ratio values of 2 and 4. This indicated the formation of  $[Pt_2Cl_6]^{2-}$  (or a soln. of  $Pt_2Cl_6$ ) and  $Pt_2$ . On a Gibbs triangle were investigated 5 sections in which the reactants were at equal concns., their sum ranging from 0.0002 to 0.001 mol./l. and 15 sections with variable  $KI:Pt$  ratio varying from 0.09 to 21; thus 75 points were fixed on the diagram. A space diagram constructed from these results comprised 2 folds. Of these the larger one occupied almost the entire area of the triangle, it had a fairly sharp peak with a max. along a line corresponding to  $KI:Pt = 2$ . The 2nd fold was low and obtuse, and its

geometry was characteristic of incongruent compns. Between these 2 folds was a trough the lowest line of which represented the geometric location of the isobaric points of  $Pt_2$ . Along this line  $Pt_2$  pptd. completely; on either side of this line the soly. of  $Pt_2$  increased. The phase diagram indicated that at concns. up to 0.001 mol./l. were formed 2 chem. compns.,  $[Pt_2Cl_6]^{2-}$  and  $Pt_2$ . The presence of an excess of  $Cl^-$  added as  $NaCl$  did not affect the tendency of  $I^-$  to replace  $Cl^-$ , although large concns. of  $NaCl$  did change the shape of the diagram. Next was studied the soly. of  $Pt_2$  in the system  $Pt_2-KI-H_2O$ . Attempts at synthesizing  $Pt_2$  by methods described in the literature were unsuccessful. In the presence of  $I^-$  quadrivalent  $Pt$  was reduced to divalent and the formed  $I$  volatilized. To obtain pure  $Pt_2$ , a soln. of  $KI$  was added to a soln. of  $(NH_4)_2PtCl_6$ ; 4 mols. of  $KI$  were used for each  $Pt$ . The mixt. was kept in a tightly closed container leaving no more than 1 cc. of air above the soln. The reaction lasted several days after which the supernatant liquid became clear.  $Pt_2$  was filtered off, thoroughly washed, and dried at  $100^\circ$ . The soly. curve comprised 2 branches. The 1st of these corresponding to  $Pt_2$  in the solid phase rose sharply with increasing concn. of  $KI$  in soln. until the latter was 0.6 mol./l. At this point  $Pt_2$  transforms into  $K_2Pt_2$  represented by the 2nd branch of the curve. The soly. of the complex salt decreases with the increasing  $KI$  concn. until it reaches practically zero when the soln. is satd. with  $KI$ . Based on the foregoing, the following procedure is recommended for detg.  $Pt_2$ . Have the analytical soln. neutral, add 5 ml. of  $10\%$   $KI$  soln., and allow to stand for 1 hr. Dil. to desired vol. and take a photorec. colorimeter reading. Det. concn. from a calibration curve prepd. from 0.001 M  $(NH_4)_2PtCl_6$  using 0.2-10 ml. of  $Pt_2$  for individual points on the curve. Cf. C.A. 40, 7038P; -44, 2402i, 2683f. M. Honeh

New method for separating noble metals from base metals with the aid of liquid amalgams and simultaneously utilizing them for determining iron, copper, and nickel. I. V. Tsiganov and M. I. Levina. *Izvest. Sektsiya Plitiny i Druzhba Blagorod. Metal., Inst. Obshch. i Neorg. Khim., Akad. Nauk S.S.S.R.* No. 22, 116-20 (1949). This method is based on reducing the noble metals to the metallic state, Cu either to metal or to the univalent state, and Fe to the bivalent state. Fe, Cu, and Ni are then detd. titrimetrically. The reduction is effected by Zn, Pb, or Bi amalgams. Zn and Pb amalgams reduce the noble metals and Cu to metals, and Fe<sup>+++</sup> to Fe<sup>++</sup>. The reduction is carried out in dil. H<sub>2</sub>SO<sub>4</sub> and Fe<sup>++</sup> is then titrated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> without filtering the soln. Another sample after soln. is reduced with Bi amalgam in dil. HCl. This reduces the noble metals to metal, and Cu and Fe to a lower valency. The sum of the 2 is titrated with K<sub>2</sub>Cr<sub>2</sub>O<sub>7</sub> and Cu is found by difference. Ni is detd. by titration with an alk. soln. of dimethylglyoxime. This titration is carried out in an aliquot of the H<sub>2</sub>SO<sub>4</sub>-reduced soln. after blocking the Fe with NaF or KF, and buffering the soln. with Na acetate. M. Hoesel

Physicochemical analysis of systems significant in analytical chemistry. XVI. Study of the kinetics of palladium iodide coagulation by means of light absorption. I. V. Tatarsov (Acad. Sci. U.S.S.R.). *Zhur. Anal. Khim.* 4, 120-45 (1949); cf. *C.A.* 44, 479a. — Since the light absorption of a system contg. a ppt. is greatly affected by the degree of dispersion of a system contg. a sol. a study of the light absorption of a system contg. a ppt. and a dispersant. The systems studied were  $\text{PdI}_2\text{-LiCl-H}_2\text{O}$  and  $\text{PdI}_2\text{-KI (excess)-LiCl-H}_2\text{O}$ . In the former, at small concns. of LiCl (or 0.05 mol./l.), the light absorption was not affected by time, remaining const. for 24 hrs. Above 0.05 mol./l., the system underwent various changes during 1 hr. until the ppt. settled out leaving the soln. clear. At still higher concns. of LiCl the rate of coagulation increased, reaching a max. of 2 min. As the rate of coagulation increased, the max. extinction value rose to a max. and then dropped sharply. Projected in space, the system is delineated by 2 planes formed by LiCl concns. of 0.05 and 2 mol./l. and more. Within these planes the system is static whereas in the space between them the system is highly dynamic. In the system contg. KI (excess), the max. extinction value for any one system was higher than for a comparative system contg. no KI. Also, the drop of extinction max. was slower in systems contg. KI. In a system contg. a ppt. its precipitant, and an outside electrolyte, the interaction between them is quite obvious but the quant. relation is as yet unknown. When coagulation is studied with the aid of light

Inst. Gen. + Inorg. Chem. im. Kurnakov,  
AN SSSR

absorption, stirring is of importance. Stirring does not affect the max. of light absorption, but when this point is reached the stirring becomes paramount. This is primarily due to the mutual attractive forces of individual particle of the ppt. and the distance between these particles.

**Solubility of silver bromate in electrolyte solutions.**  
 1. The system silver bromate-alkaline earth metal nitrate-water. I. V. Tananayev, Yu. L. Le'chuk, and B. Kh. Petrovichaya (White-Russ. Polytech. Inst., Minsk). *Zhur. Obshch. Khim.* (J. Gen. Chem.) 19, 1307-15 (1948); cf. C.A. 41, 3239a. — Data for  $M(NO_3)_2$  solns. ( $M = Mg, Ca, Sr, Ba$ ) of  $AgBrO_3$  at 25° at nitrate concns. up to 1 *M* are tabulated, giving the concn. of  $M(NO_3)_2$ , the molarity of  $AgBrO_3$  in satd. soln., ionic strength *s*, activity coeff.  $\gamma$ , soly. product *L<sub>p</sub>*, activity product *L<sub>a</sub>*, and activity *a*. The calcns. are based on the following relations:  $[Ag^+] \times [BrO_3^-] \gamma^2 = L_p a_{AgNO_3} \gamma^2 = L_a a_{MNO_3}$ ;  $\gamma = \sqrt{L_a/L_p}$ ;  $-\log \gamma = 0.805\sqrt{s}/(1 + 0.32s\sqrt{s})$ . The soly. of  $AgBrO_3$  increases with increasing nitrate concn., the increase being most pronounced at high nitrate concn. The cations enhance the soly. in the order  $Mg < Ca < Sr < Ba$ , but a decrease in this same order, e.g. in 0.3 *M* soln. from 3.27 to 1.90, in 1 *M* soln. from 2.41 to 1.69. *L<sub>a</sub>* is not entirely const., it has a min. for  $M(NO_3)_2$  concn. in the region from 0.1 to 0.3 *M*. A plot of *s* against the ionic radii *r* of the cations gave an almost straight line. The soly. *S<sub>AgBrO\_3</sub>* was calcd. from  $\sqrt{L_a/L_p}$ , where *L<sub>a</sub>* (assumed to be const., as a simplification), is  $8.5 \times 10^{-9}$ ;  $\gamma$  may be calcd. from  $-\log \gamma = 0.805\sqrt{s}/(1 + 0.32s\sqrt{s})$ , where *s* is the av. (= 2.1)  $\times 10^3$  for 0.3 *M* Mg, Ca, Sr, and Ba nitrates is 1.27, 1.33, 1.43, 1.49; for 1 *M* solns. 1.73, 1.81, 1.84, —. The soly. in H<sub>2</sub>O at 25° is 0.1948 g./100 ml.; values by 10 other authors are given. Kitty Lux

TANANAYEV, I. V.

Physicochemical analysis of systems significant in analytical chemistry. XVIII. Theory of precipitation of barium sulfate from the point of view of turbidimetric analysis. I. V. Tananayev and N. A. Rudnev (Acad. Sci., U.S.S.R.). *Zhur. Anal. Khim.* 8, 82-9 (1963); cf. *C.A.* 44, 2402i. The systems studied were  $BaSO_4$ - $C_2H_5OH$ - $H_2O$  and  $BaSO_4$ - $BaCl_2$ - $C_2H_5OH$ - $H_2O$ .  $EtOH$  was used to decrease the soly. of  $BaSO_4$ , and thereby obtain a complete light-absorption curve with a clear max. Equiv. quantities of  $H_2SO_4$  and  $BaCl_2$  solns. were combined in a mixt. of  $H_2O$  and  $EtOH$ , the total vol. being 50 ml. Where an excess of  $BaCl_2$  was desired it was added simultaneously with the stoichiometric quantity of  $BaCl_2$ . The alc. in the final mixt. made up 0-50% and the excess  $BaCl_2$  was 0-0.3 M. Light absorption readings were taken at 0.5 and 1-6 min. at 1 min. intervals. The light absorption of the suspension increased sharply with the alc. content and reached a max. at 30% of alc. after which it dropped sharply. At above 50% of alc. it would reach practically zero. The drop in light absorption with an increase in the alc. content is attributed to an increase in the dispersion of  $BaSO_4$ . The behavior of light absorption in the presence of an excess of  $BaCl_2$  was analogous. More striking was the behavior of the maxima on the curves under the influence of excess  $BaCl_2$ . At first the max somewhat diminished and then rose sharply. The effect

of BaCl<sub>2</sub> is explainable by its action on BaSO<sub>4</sub>, in which case it augments the effect of KOH. This does not explain the fluctuation of the max. Excess BaCl<sub>2</sub> affects not only the dispersion of BaSO<sub>4</sub>, but apparently also its cryst. form as well as the bulk of the ppt. due to copptn. Both of these affect the light absorption. Thus, the light absorption of a BaSO<sub>4</sub> suspension is complex and depends greatly on circumstances of pptn., primarily on the alc. content and the excess BaCl<sub>2</sub>. Therefore, care must be exercised when using this method for the detn. of SO<sub>4</sub><sup>-2</sup> either with the aid of calibration curves or by turbidimetric titration. M. Hosen

Physicochemical analysis of systems significant in analytical chemistry. XIX. Investigation of the system  $H_2SO_4-NaCl-CH_3OH-H_2O$  from the point of view of turbidimetry. I. V. Lavrenko and N. A. Rubtsov (N.S. Kharkov Inst. of Gen. Chem. Phys., Chern. Acad. Sci. U.S.S.R.). *Zhur. Anal. Khim.*, 5: 281-2/1939; cf. C.A.B. 44: 4515d. The solns. studied were prepd. by adding to 12.50 ml. of 0.194 M  $H_2SO_4$  a NaCl soln., aq.  $H_2O$ , and finally BaCl<sub>2</sub> soln. to make the total vol. 50 ml. The quantity of BaCl<sub>2</sub> in all solns. was equiv. to the  $H_2SO_4$ . The concn. of NaCl was 0.1 M and the a/c. content was 0-50% by vol. From the time BaCl<sub>2</sub> was added, extinction readings were taken at definite intervals after 0.25-2 min. Time, this factor varied with the concn. of the system. By plotting time vs. extinction & types of curves were obtained depending on the a/c. and NaCl content. In the absence of NaCl turbidity did not change with time. With 0.1-1.0 M NaCl there was a decrease in extinction with time. At small a/c. content the extinction increased with time, the increase being greater as the concn. of NaCl rose. At a NaCl content of 1 M, the curve had a distinct max. Thus, NaCl retarded pptn. even at fairly high a/c. content. In the absence of a/c. pptn. was arrested completely for several min. At a high concn. of NaCl the opposing effect of the salt is more pronounced. NaCl increases somewhat the soly. of  $H_2SO_4$ , while a/c. has the opposite effect. The molar extinction coeff. corresponding to max. absorption was 142. This value coincided with the analogous value in the system  $H_2SO_4-BaCl_2-EtOH-H_2O$ . Since the effect of NaCl and BaCl<sub>2</sub> on  $H_2SO_4$  is opposite, it is evident that the degree of dispersion coincidental with max. absorption in the system  $H_2SO_4-EtOH-H_2O$  can be increased either by retarding crystal. growth, by adding an agent which enhances the soly. of  $H_2SO_4$ , or by accelerating the formation of primary particles as compared to the secondary process of their aggregation. In the former case the max. shifts to the right until it reaches its limiting value, in the 2nd case the max. shifts to the left until it attains its greatest value. It was observed that the form of the ppt. differs depending on the presence of BaCl<sub>2</sub> and NaCl. In the absence of these salts, the ppt. is loose and flaky, while in the presence of BaCl<sub>2</sub> or NaCl the crystal structure is pronounced.

Cryolite Method for the Determination of Aluminium in  
Complex Alloy Steels and Other Alloys. I. V. Tananay and  
P. Ya. Yakovlev. (Zavodskaya Laboratoriya, 1950, 16, (10),  
1155-1161). [In Russian]. An account is given of a gravi-  
metric method for the determination of aluminium in steels  
as well as in iron and nickel-base alloys containing chromium,  
molybdenum, tungsten, vanadium, zirconium, niobium, and  
titanium. The aluminium is precipitated as cryolite and test  
data are presented showing the effect of each of the above  
elements on the precipitation. Results of aluminium  
determinations in steels and alloys by the cryolite method  
agree well with those obtained by the slower mercury-  
cupferron method.—H. X.

TARANAYEV, I. V.

The activity of solution components in liquid hydrogen fluoride. I. N. S. Nikolaev and I. V. Taranayev. *Izv. Sektora Fiz.-Khim. Anal., Akad. Nauk S.S.S.R.* 20, 184-185 (1950).—The activity ( $a$ ) was calcd. from the basic equations of Lewis and Randall. Metzger and Klatt (*C.A.* 31, 8259) found in detns. of vapor pressure depression that HF mols. in the liquid state associated into  $[HF]_2$ . Dahmos and Jung (*C.A.* 27, 4148) found in m.p. detns. that HF existed as  $[HF]_2$ . Thus,  $\Delta H$  (latent heat of vaporization) was taken to be 6160 cal, and the latent heat of fusion 4048 cal. The freezing point depression was calcd. to be 1.3° and the b.p. rise 1.0°.  $a$  was detd. cryoscopically and ebullioscopically with KF, NaF, and LiF solns. in and ebullioscopic detns. could be made for KF up to 10M, for NaF up to 5M, and for LiF up to 2.8M. Above these concns. boiling stopped. On curve of the activity coeff. ( $f$ ) of HF vs. concn. of solute the curves of KF and NaF had a max. beyond which they dropped sharply and approached asymptotically concns. corresponding to KF·5HF and NaF·10HF, resp. The LiF curve had no max. nor did it have an asymptotic branch but ended at a point corresponding to LiF·20HF. The sharp drop of  $f$  and the in-

terruption of boiling point is a peculiar condition apparently brought about by the formation of the acid salts. The ascending part of the curve (before reaching the max.) points to a break-up of the aggregated mols. as suggested by Getman and Daniels. From a math. analysis of the curves were found the following relationships between the  $f$  and the concn. of the solute  $-68.03N_{KF} + 44.705N_{NaF} + 5.149N_{LiF} - 1.184N_{KF} + 1 = f_{NaF}$ ,  $-934.745N_{NaF} + 490.860N_{LiF} - 78.73N_{NaF} + 2.769N_{LiF} + 1 = f_{LiF}$ , and  $-1824.254N_{LiF} + 550.523N_{NaF} - 48.890N_{LiF} + 0.331N_{NaF} + 1 = f_{LiF}$ . A comparison between calcd. and exptl. values showed a relative difference for  $f_{NaF}$  in KF solns.  $\pm 0.85$ , in NaF  $\pm 0.62$ , and in LiF solns.  $\pm 0.66\%$ . II.

Activity of alkali fluorides in liquid hydrogen fluoride. N. S. Nikolaev. *Ibid.* 196-203.—In this investigation was calcd. the relationship between the activity coeff. of HF and the activity coeff. of KF, NaF, and LiF. The results are tabulated and presented graphically. The results indicate the multimol. nature of HF. The dissolved fluoride reacts first with HF monomers until they are used up. During this stage the activity coeff. of the solvent decreases. Further increase in the concn. of the solute causes breakup of HF polymers. At this stage the activity coeff. of the solvent increases and of the solute decreases. This proceeds until all of the HF polymers disappear. At this point sets in a satd. compn. which for KF is KF·5HF, and some excess solvent is also present. A rise in temp. drives off this excess and the acid salt begins to dissociate. The effect of alkalis on the disaggregation of HF polymers is  $K > Na > Li$ . III. Activity of hydrogen fluoride in ammonium base solutions. N. S. Nikolaev and I. V. Taranayev. *Ibid.* 204-11.—Activity and activity coeffs. were studied in the systems  $NH_3$ -HF,  $C_2H_5NH_2$ -HF,  $CH_3NH_2$ -HF, and  $(C_2H_5)_2NH$ -HF. Exptl. (ebullioscopic) and calcd. values of  $f$  for these systems are tabulated. The calcs. were made on the basis of  $[HF]_{2-4}$ , mol. wt. 69. The accumulated data show a striking correspondence between  $f_{max}$  and  $f_{min}$ .  $\rho$  is the ratio of mol. rise in boiling temp. to the ebullioscopic const. of HF which is taken to be 1.9 (cf. Fredenhagen and Cadenbach, *C.A.* 27, 3381). Thus e.g., for  $NH_3$ -HF  $\rho_{min} = 0.345$ , and this corresponds to  $f_{max} = 1.29$ . The facts that  $\rho < 1$  and  $f > 1$  is taken to indicate that there is an increase in the active mass of the solvent.  $f_1$  was plotted vs.  $N_1$ , the mole fraction of solute, and from these curves were calcd. the coeffs. A, B, C, and D in the equation for  $f_1$ . Generally, the values of  $f_1$  calcd. from the empirical equation were close to those obtained by expt., but in some parts of the studied systems the differences were considerable. The limiting compds. for the studied systems were  $NH_3$ ·5HF,  $C_2H_5NH_2$ ·7HF,  $CH_3NH_2$ ·10HF, and  $(C_2H_5)_2NH$ ·16HF. M. Hoesch

TANANAYEV, I. V.

Physicochemical analysis of systems significant in analytical chemistry. XXII. Investigation of solubility in the system  $AlF_3$ - $KF$ - $H_2O$  at 25°. I. V. Tananayev and M. A. Neklankina. *Izvest. Sektora Fiz.-Khim. Anal., Akad. Nauk S.S.S.R.* 20, 227-37(1950); cf. *C.A.* 46, 3384g. — Solns. of  $AlF_3$  and  $KF$  were mixed in such a manner that at a const. vol. of 200 ml, the ratio of  $KF:AlF_3$  increased from 1:1 to 1:80. The mixts. placed in a thermostat were stirred for 8 hrs. and then allowed to settle. The supernatant clear liquid and the ppt. were analyzed for K and Al. In the mixed soln. a ppt. formed throughout the entire range of  $KF:AlF_3$  ratios starting with 1. As the  $KF:AlF_3$  ratio reached 8, no Al could be detected in the liquid phase. At  $KF:AlF_3$  ratios from 1 to 15 the solid phase formed was  $2KF \cdot AlF_3 \cdot H_2O$ . At ratios from 15 to 40 solid solus. formed having a gradually increasing  $KF$  content. At ratios 40-80  $3KF \cdot AlF_3$  formed.  $2KF \cdot AlF_3 \cdot H_2O$  was stable in contact with  $H_2O$  and dissolved congruently.  $3KF \cdot AlF_3$  dissolved incongruently and was decompd. by  $H_2O$  into  $2KF \cdot AlF_3 \cdot H_2O$ , forming a ppt. and  $KF$  which dissolved. The thermogram of  $2KF \cdot AlF_3 \cdot H_2O$  showed 4 steps: at 145-165° an endothermal effect connected with the loss of  $H_2O$  of crystn., and exothermal at 230-260° apparently occasioned by recrystn. of the anhyd. double salt, at 570-610° apparently occasioned by partial decompn. of the salt, and an endothermal at 855°, the m.p. of the salt. The thermogram of  $3KF \cdot AlF_3$  had 5 stops. Of these 160-185°, 285-315°, 575-585°, and 1030° are analogous to the stops on the  $2KF \cdot AlF_3 \cdot H_2O$  thermogram. The stop at 505-520° is as yet unexplained. The soly. of  $2KF \cdot AlF_3 \cdot H_2O$  in  $HF$  was studied. At  $HF$  concns. above 43% the reaction proceeds according to  $2KF \cdot AlF_3 \cdot H_2O + HF \rightarrow KF \cdot AlF_3 + KHF_2 + H_2O$ . At  $HF$  concns. below 40%, the reaction is reversed. M. Hoesch

TANANAYEV, I. V.

Physicochemical analysis in analytical chemistry. I. V. Tananayev. *Izvest. Sektsia Fiz.-Khim. Anal., Akad. Nauk S.S.S.R.* 20, 277-93 (1954).—The importance of phys.-chem. analysis in explaining analytical methods is discussed. In pptn. procedures the soly. of the ppt. in the presence of similar and dissimilar ions can be studied only by methods of phys.-chem. analysis. The ionic strength of a soln. calcd. on the assumption of complete dissoen. of an electrolyte is justified at best for uni- and bivalent electrolytes. For tri- and quadrivalent electrolytes hydrolysis enters into play, resulting in the formation of free acid and of practically undissoc. ions of the type  $M(OH)^{+++}$ ,  $M(OH)_2^{++}$ , etc. Under such conditions the calcs. are no longer reliable. Also in the presence of extraneous salts, the compn. of the ppt. is variable as solid solns. and double salts are likely to be formed. The study of the behavior of a given salt as part of a ternary, quaternary, or multicomponent system is valuable in the understanding of its analytical behavior. Light adsorption, electrocond., e.m.f., thermal analysis, and measuring the vol. of a ppt. of systems are invaluable in developing analytical methods. M. Hosen.

**New titrimetric procedure for determining potassium.**  
 I. V. Tananay and A. S. Kozlov. *Zhur. Anal. Khim.* 6, 119-120 (1951). This method is based on the interaction of  $\text{CdSO}_4$ ,  $\text{Li}_2\text{Fe}(\text{CN})_6$ , and  $\text{K}_4\text{Fe}(\text{CN})_6$ . The first two react to form  $\text{Cd}_2\text{Fe}(\text{CN})_{12}$  regardless of the excess  $\text{Li}_2\text{Fe}(\text{CN})_6$ . The system  $\text{CdSO}_4$ - $\text{K}_4\text{Fe}(\text{CN})_6$ - $\text{H}_2\text{O}$  behaved quite differently. Up to a  $\text{K}_4\text{Fe}(\text{CN})_6$ : $\text{CdSO}_4$  ratio of 0.3  $\text{Cd}_2\text{Fe}(\text{CN})_{12}$  is formed. At a ratio of 0.3-0.7 a variable solid phase is formed containing 0-0.9 mol. of  $\text{K}_4\text{Fe}(\text{CN})_6$  per mol. of  $\text{Cd}_2\text{Fe}(\text{CN})_{12}$ . The complex reaction product is  $5\text{Cd}_2\text{Fe}(\text{CN})_{12} \cdot 4\text{K}_4\text{Fe}(\text{CN})_6$ . In the 3rd stage as the  $\text{K}_4\text{Fe}(\text{CN})_6$  increases further, the double salt  $\text{Cd}_2\text{Fe}(\text{CN})_{12} \cdot \text{K}_4\text{Fe}(\text{CN})_6$  is formed. Thus, after pptg. Cd with  $\text{Li}_2\text{Fe}(\text{CN})_6$ , the excess of the latter can be detd. by titration with  $\text{KMnO}_4$ . Addn. of a K salt, e.g.  $\text{KCl}$  or  $\text{KNO}_3$ , will cause  $\text{K}_4\text{Fe}(\text{CN})_6$  to be absorbed on the Cd ppt. and form  $5\text{Cd}_2\text{Fe}(\text{CN})_{12} \cdot 4\text{K}_4\text{Fe}(\text{CN})_6$ . The amt. of  $\text{Fe}(\text{CN})_6^{4-}$  in soln. will thereby be reduced. A 2nd titration with  $\text{KMnO}_4$  will indicate the amt. of  $\text{Fe}(\text{CN})_6^{4-}$  removed from soln. and can be recalc. in terms of K.

"Zhur Obshch Khim" Vol XXI, No 12, pp 2235-2245

Studied systems  $Al(NO_3)_3-HF-H_2O$ ,  $AlCl_3-HF-H_2O$ ,  $Al(SO_4)_3-HF-H_2O$  using methods in H<sup>+</sup> ion concn and thermometric measurements. Found that in all 3 systems very stable  $AlF_2^+$  ions, not noticeably dissociated in soln, are formed. Their existence is explained by ability of salts of Al and many other polyvalent metals to dissolve difficultly soluble fluorides (cryolite,  $CaF_2$ ). Existence of  $AlF_3$  or complex fluoroaluminates of type  $AlF_6^{3-}$  could not be confirmed due to their high deg of dissociation. These data compel a change in views on state and behavior of polyvalent metallic fluorides in soln.

Inorganic Chemistry

The reaction between bivalent manganese ions and  $K_4Fe(CN)_6$ . I. V. Tananayev and E. S. Dzhanogly, *J. Gen. Chem. U.S.S.R.* 21, 1097-1103 (1951) (Eng. translation); *Zhur. Obshchek Khim.* 21, 1000-10 (1951).—The soly. and cond. of mixts. of  $MnSO_4$  and  $K_4Fe(CN)_6$  in water were studied.  $MnK_4Fe(CN)_6$  (I) is less sol. than  $Mn_3Fe(CN)_6$ , and under most conditions I is the solid phase at 25°. One of the principal factors affecting the compn. of the solid is the concn. of  $K^+$ , which depends on the amount of  $K_4Fe(CN)_6$  added. When the total concn. of  $MnSO_4$  and  $K_4Fe(CN)_6$  is less than 0.03M, and the ratio  $K_4Fe(CN)_6:MnSO_4$  in the mixt. is small, the solid phase is  $Mn_3Fe(CN)_6$  contaminated with I. No  $Mn_3Fe(CN)_6$  is pptd. at higher concns., regardless of the ratio of reactants, or at concns. as low as  $6 \times 10^{-4}M$  at ratios of 1.25 or greater. The cond. curve at all concns. passes through a min. at unity ratio, which corresponds to the compn. of I. Analyses of 0.0156M  $MnSO_4$  solns. show that the solid is I at  $K_4Fe(CN)_6:MnSO_4$  ratios between 0.128 and 0.170. Soly. and cond. data indicate no solid solns. are formed. Addn. of  $K_4Fe(CN)_6$  to  $MnSO_4$  produces a sol very sharply at unity ratio. Several methods for the analysis of  $Mn^{++}$  are suggested by gravimetric, volumetric, potentiometric, turbidometric, and conductometric methods based on the formation of I.
