Title : "Fixed" Rh Antibodies in the Method of Their Investigation.

Orig Pub: Labor. delo, 1956, No 4, 14-18.

Abstract: Different types of Rh antibodies are described; the mechanism of their action is considered; a method of determination of "fixed" or monovalent Rh antibodies is introduced. The preparation of antiglobulin serum and its application in clinical demonstration of Rh sensitization is discussed (Coombs test, modified by Umhova).

PROBLEMS AND PROSPECTS INDEX	
VAKIN (A. T.) K voprosu o opredelenii usloviy zashchity <i>o zashchite neperedannym. [On the problem of the preservation of summer-felled logs from fungal injury.] - ex <i>Грибовыя загрозы в лесном хозяйстве. Сборник работ Лаборатории Хранения Дровицы ЦНИИМОДа, I [Diseases to timber caused by fungi. Collections of the Works of the Laboratory for Timber Storage of ZNIIIMOD, I],</i> pp. 10-92, 13 figs., Toch. Akad. Text. Wydat. [State Forestal Tech. Publ. Office], Moscow, 1931.</i>	
<p>This is a detailed account of large-scale experiments in 1931 in the neighbourhood of Moscow to determine the conditions that are least conducive to the development of blue staining and other lignicolous moulds, and of fungal rots, in summer-felled pine and fir logs stored <i>in situ</i>. Comprehensive notes are given on the more important fungi that were observed locally to cause blemishes and decay in the logs, the symptoms produced being briefly described. These are superficial blue staining caused by <i>Chloropeltis herbarum</i> and <i>Aleuria lepida</i> on both kinds; deep penetrating blue stains in both pine and fir caused by <i>Ceratostomella pini</i>, <i>C. pini</i>, <i>C. coriaria</i>, <i>C. imperfecta</i> n.sp. [see next abstract], and <i>Hormonema denudans</i> [R.I.M., XIV, p. 68]; and in pine alone by <i>Endoconidiophora corynevens</i> [loc. cit.]; a reddish-brown (cacao-coloured) slow rot caused very commonly in fir but more rarely in pine by <i>Stereum sanguineum</i>; and a coffee-coloured one, more especially in pine, caused by a mycelium which has not yet been identified.</p>

ned. Among the other fungi isolated special mention is made of a deep-seated, yellowish-pink or light orange discolouration in streaks, associated with fruiting bodies of *Corticium levi*, light brown or whitish, frequently water-soaked discolourations caused by *Pinophoma gigantea* [ibid., vni, p. 3], and a very slow, dirty grey, wet rot caused by *Schizophyllum commune*. A passing mention is finally made of very superficial yellow, delicate pink, cherry-coloured, and purple discolourations caused by moulds such as *Fusarium* and *Penicillium* spp., which, however, did not affect the properties of the timber and usually disappeared entirely as the wood dried.

While it is freely admitted that experiments during one season alone are not conclusive, the results of the main investigations indicated that effective protection against infection with these fungi, and also against too rapid desiccation leading to the formation of cracks in the timber and from attacks by bark-boring insects, was afforded by piling the unbarked pine and fir logs on low supports or directly on damp earth not later than 15 days after felling, into compact piles of 20 to 30 logs or more, and covering them with a thick layer of conifer branches; this should be supplemented by painting the cut ends of the logs with either 3 per cent. sodium fluoride or a 3 to 5 per cent. iron sulphate solution. Fir logs showed also little injury when they were stripped of the outer bark down to the bast, which should be left as uninjured as possible, and stored in loose piles, each row of logs being separated from the next by transverse supports.

During their work in 1947 and 1948 in the Teberdin and Caucasus State Forest Preserves and in the forests in the Stavropol and Krasnodar districts, the authors studied the bracket fungi occurring on Caucasian fir (*Abies nordmanniana*) in mature and old stands. The most common species were *Fomes robustus* [R.I.M., 15, p. 68], which is destroying the wood of trees 200 years old or over; *Polyporus berkeleyi* [ibid., 11, p. 680] at high altitudes, causing a root rot; and *P. dryadeus* [ibid., 9, p. 749; 11, p. 680], causing a rot of the roots and the lower trunk.

"Propagation of Electromagnetic Waves Along an Infinite Spiral Slot", S. A. Vakin

"Dok Ak Nauk SSSR" Vol LXXXIV, No 1, pp 37-41

Considers the conditions under which electromagnetic waves can be propagated along an infinite cylinder of circular cross section with ideally conducting walls of infinitely small thickness. The cylinder is placed in a homogeneous isotropic medium without losses and has a narrow slot of fixed width cut in a spiral along its walls. Prof Ya. N. Fel'd was responsible for scientific direction of the work. Submitted by Acad M. A. Leontovich 1 Mar 52.

SOV/108-13-7-11/14

TITLE:

On the Measuring of Complex Resistances by Means of a Feeder-
Reflectometer (Ob izmerenii kompleksnykh soprotivleniy s
pomoshch'yu fidernogo reflektometra)

PERIODICAL:

Radiotekhnika, 1958, Vol. 13, Nr 7, pp. 76-79 (USSR)

ABSTRACT:

A method of measuring complex resistances is investigated, which is based upon the use of the feeder-reflectometer developed by A.A.Pistol'kors and M.S.Neyman, and modernized by B.G.Strausov. The analysis of the reflection of electromagnetic waves of heterogeneities in the line, which was carried out by the authors, showed that, with the aid of a reflectometer, it is possible to carry out measurements not only of the modulus but also of the phase of the reflection factor. Phase-measurement is based upon a certain dependence of the reflection factor on the investigated load P_Z , the reflection factor of the investigated load P_{ZR} shunted by the resistance R , and the reflection factor P_R of the gauged resistance shunted by the wave resistance of the line under investigation. The connection existing between these factors can be determined by the method of analyzing heterogeneities in

Card 1/2

On the Measuring of Complex Resistances by Means
of a Feeder-Reflectometer

SOV/ 108-13-7-11/14

the lines. The determination of resistances is carried out on the basis of two measurements of the modulus of the reflection factor. The equation (17) is derived which makes it possible to determine the phase of the reflection factor φ with an accuracy of up to 180° . The absolute error in measurements of the phase of the reflection factor in the case of the method dealt with here depends on the measuring errors of the reflectometer ; as shown by experiments, this absolute error does not exceed $\pm (5 - 7)\%$ at $P_Z \geq 0.5$. For the determination of the effective- and blind component of the complex resistance according to known P_Z and φ circular diagrams of the resistances (nomographs by Vol'pert) are used. The method described can be widely used for the purpose of measuring input resistances of antennae, receiving sets, filters, and other four-pole circuits of the shortwave range. There are 2 figures, and 3 references which are Soviet.

TITLE: Direction-finding characteristics of monopulse automatic-tracking systems

SOURCE: IVUZ, Radiotekhnika, v. 8, no. 5, 1965, 550-560

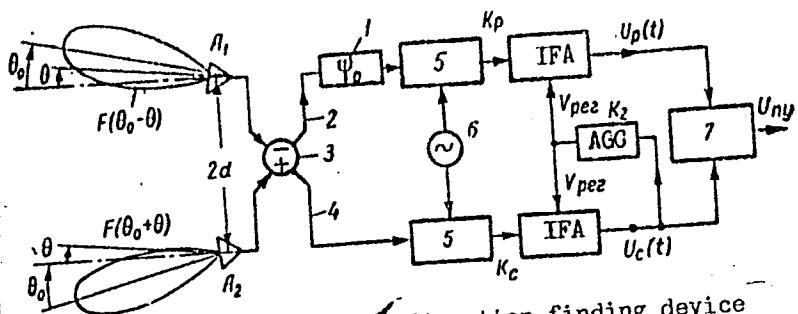

TOPIC TAGS: monopulse radar, automatic tracking

ABSTRACT: The well-known Hellgren's direction-finding characteristics are based on ideal operation of the AGC system. Under real conditions, the phase-detector output voltage depends on the strength of the input signal. The present article develops formulas describing the direction-finding characteristics with an allowance for the real AGC-system operation. A generalized scheme (see figure below) is considered: Both amplitude and phase direction-finding characteristics show that the major-lobe width is independent of the AGC equivalent transfer factor ρ' . This factor, however, has an essential influence on the slope of the direction-finding characteristics and on the spacing between the maxima when $\rho' < 10-20$. With

TITLE: Effect of X-ray irradiation upon the content of glycogen and reducing compounds in yeasts

PERIODICAL: Mikrobiologiya v. 31, no. 4, 1962, 577-581

TEXT: This is a continuation of previous studies. Carbohydrate metabolism in irradiated yeasts was insufficiently studied until now. Sacch cerevisiae, Sacch. Frohberg carlsbergensis and Sacch. carlsbergensis 10-D. were x-irradiated with 10-200 cu at a dose rate of 800 r/min in pressed and sterile conditions, and grown on agar for 24, 48, 72 and 96 hours. Non-irradiated cells were grown under similar conditions. A very large inoculum was used. The glycogen content in the irradiated cells decreased (from 60 to 90%) in all three strains. Immediately after irradiation the glycogen content decreased only to 5-8%. An average increase of 30-35% in the content of reducing compounds was observed in the irradiated and grown yeast cells. This increase was found also in cells immediately after irradiation with 20-25 cu. Irradiation with 200 cu, resulted in an increase in reducing compounds by about 50% as compared with the controls. There are 2 figures and 3 tables.

TITLE: Using nonlinear elements in correlators

SOURCE: Vsesoyuznaya nauchnaya sessiya, posvyashchennaya Dnyu radio. 22d, 1966.
Sektsiya radiotekhniki. Doklady. Moscow, 1966, 20-33

TOPIC TAGS: signal correlation, correlation statistics, nonlinear effect

ABSTRACT: The properties of a correlator based on a nonlinear element (detector) whose characteristic is described by the equation:

$$Z = \begin{cases} ay & y \geq 0 \\ 0 & y < 0. \end{cases}$$

are investigated. The S/N ratio at the output of this correlator is analyzed as a function of: reference signal whose amplitude is fairly large in comparison with the signals which follow, a signal whose relationship to the reference signal is non-stationary, and the external noise which is uncorrelated with the other two signals. The analysis assumes that the processes are confined to a narrow frequency band, are Gaussian with average value of zero, and have symmetrical spectra. The S/N of this correlator detector is compared to that of the ideal correlator. A loss coefficient Card 1/2

ACC NR: AT6022237

is introduced which relates the S/N of the detectors with and without noise due to detection process for the cases when the input signal has a rectangular spectrum, when it is similar to that of a simple ringing circuit, and when it is similar to a band-pass filter spectrum. Orig. art. has: 27 formulas and 6 tables.

TITLE: Effect of certain factors on the photooxidation of hydroxylamine in isolated chloroplasts

SOURCE: Bulgarska akademiya na naukite. Doklady, v. 18, no. 7, 1965, 659-662

TOPIC TAGS: chloroplast, hydroxylamine, photooxidation, enzyme, plant chemistry, chlorophyll

ABSTRACT: The authors established earlier that in isolated chloroplasts there occur processes of photooxidation of hydroxylamine to nitrile (Compt. rend. Acad. bulg. Sci., 17, 1964, no. 3, 283) accompanied by absorption of molecular oxygen (Ibid., 17, 1964, no. 11, 1051). Hydroxylamine seemed to be the donor of electrons in a reaction catalyzed by light, and the final acceptor was the molecular oxygen. The present paper deals with the changes in the oxidation rate of hydroxylamine due to the substrate of the reaction (NH_2OH), the chlorophyll concentration, the pH of the chloroplast suspension, and the temperature. All results seem to indicate that the photooxidation of hydroxylamine is a light-induced enzyme process. This paper was presented by Academician Emanuiloff on 20 March 1965. TITLE: Influence of temperature on the reduction of nitrite in higher plants in light and in darkness

SOURCE: Bulgarian akademiya na naukite. Doklady, v. 18, no. 7, 1965, 671-674

TOPIC TAGS: nitrite, plant chemistry, chlorophyll, low temperature effect, enzyme, photosynthesis

ABSTRACT: It is currently believed that the photoreduction of nitrite is an enzymatic and not a purely photochemical process (E. Kessler, in "Research in photosynthesis", Interscience Publishers, Ltd, London; N. P. Voskresenskaya, Dissertation). To elucidate this problem, use is usually made of low temperatures delaying the enzymatic effect without affecting the photochemical reactions. The present article contains data about the influence of temperature on the speed of the reduction under light or in darkness of nitrites in leaves of higher plants. This investigation also made use of chlorophyll-less leaves which are a convenient model for studying the nitrite reduction during exposure to light as compared with that in normal green leaves. The results obtained show that raising the temperature increases the reduction speed of both nitrates and nitrites. This leads the authors to

Card 1/2

L 30182-66

ACC NR: AP6020316

believe that this is also the case of plants cultivated on soil, though the effect is obscured by the nitrites obtained as a result of the more intense reduction of the existing nitrates at the higher temperatures. The delaying influence of low temperature is particularly pronounced in nitrite reduction in chlorophyll-less leaves during exposure to light and during the reduction of green leaves in darkness. TITLE: The Influence of the Form of Nitrogen Upon the Accumulation of Chlorophyll and Upon the Oxidative System in Zea mays L.
(Vliyanije formy azota na nakopleniye khlorofilla i okislitel'nyyu sistemu kukuruzy)

PERIODICAL: Doklady Akademii Nauk SSSR, 1958, Vol. 119, Nr 1, pp. 129-132
(USSR)

ABSTRACT: Several works (references 1-3) are devoted to the investigation of different doses of nitrogen as a factor influences the intensity of photosynthesis as well as the nature of the products of the latter. The problem of the influence of different forms of nitrogen mostly was not taken into consideration. From publications (references 4-8) is known that by a nitrate food the quantity of organic acids in the plants increases as compared to plants with ammonia food. N. S. Turkova (ref. 9) advocates an opposite opinion. The object of the present paper was the investigation of the influence of these two forms of nitrogen food upon the quantitative content of dyes and upon the activity of some oxidative-reductive processes. The experiments were performed

Card 1/4

The Influence of the Form of Nitrogen Upon the Accumulation
of Chlorophyll and Upon the Oxidative System in Zea mays L. 20-119-1-35/52

in 2 series: series I. Maize plants were cultivated in light
as liquid cultures. The variants were: 1) control - in water
without addition of nitrogen; 2) on nitrate-nitrogen as
 NaNO_3 ; 3) on ammonium nitrogen as $(\text{NH}_4)_2\text{SO}_4$. Series II. The
influence of NO_3^- and NH_4^+ upon the greening of the plants was
determined. The variants were as in series I. The plants were
kept in the dark for 5 days and then put into the light. As
is to be seen from table 1 the influence of both forms of
nitrogen upon the development of the plants is unequal. The
plants on nitrate-nitrogen developed best. As well the weight
as the length of the stem superior to those of the plants
with ammonia-nitrogen. Both forms of nitrogen suppress the
length of the roots the weight of which, however, exceeds
that of the control (agrees with reference 13). In the case
of nitrate-nitrogen-food the quantity of a- and b-chlorophyll
in all tests was higher than in the control- and ammonia-
-plants (table 2). The latter plants, cultivated in the light,
exceeded the control plants with regard to the chlorophyll
content. But when these plants were first kept in the dark
and then brought into the light, their quantity of chlorophyll
was considerably smaller than in the control. The ratio

Card 2/4

The Influence of the Form of Nitrogen Upon the Accumulation 20-119-1-35/52
of Chlorophyll and Upon the Oxidative System in Zea mays L.

between a- and b-chlorophyll independent on the illumination decreases by nitrate-nitrogen and increases by ammonia-nitrogen. That means that the more intensively oxidized chlorophyll-form (form b) is synthesized on nitrate nitrogen. The activity of the oxidative enzymes may, so to speak, serve as index of the oxidative-reductive regime in the plant tissues. Table 3 shows that the activity of the catalase and peroxydase as well in the leaves as in roots is higher in plants which were cultivated on ammonia-food. In order to find out whether this increased activity has to compensate the lack of active nitrate-oxygen in the plant, experiments were performed in which part of the plants was continuously exposed to the air, whereas the other part was cultivated under oxygen deficiency. Table 4 shows that the plants on nitrate nitrogen thrive very well even without additional exposure to the air. But in plants on NH₃ without exposure to the air of the organs above the ground the growth of the latter and that of the roots is retarded (in agreement with reference 14). The activity of the catalase decreases in the variant with nitrate nitrogen, where the chlorophyll

Card 3/4

The Influence of the Form of Nitrogen Upon the Accumulation
of Chlorophyll and Upon the Oxidative System in Zea mays L. 20-119-1-35/52

synthesis takes place more intensively (ref. 15). In contrast to this polyphenoloxidase is more active in plants fed with nitrates. This only refers to leaves, as this activity in the roots of ammonia plants is higher (table 5). The results of series II are given in table 6. The plants green faster on the nitrate form than on ammonia. For the quantity of the ratio between chlorophyll a and b the previous influence of the dark is of no importance. Chlorophyll a is faster synthetized, the ratio between the two forms on nitrate nitrogen always remaining smaller than on ammonia nitrogen. The absolute quantities of chlorophyll a and b decrease with the lengthening of the duration of the stay in the dark. There are 6 tables and 15 references, 13 of which are Soviet.

TITLE: The Effects of Different Nitrogen Forms on the Composition of Labelled Photosynthetic Products in Maize and Phaseolus (Vliyaniye raznykh form azota na sostav mechenykh produktov fotosintezu u kukuruzy i fasoli)

PERIODICAL: Doklady Akademii nauk SSSR, 1956, Vol 122, Nr 4, pp 653 - 656 (USSR)

ABSTRACT: Initially, various factors are discussed which influence the distribution of the photosynthetically assimilated carbon (Refs 1-7). Under these conditions, an improved nitrogen nutrient is said to increase the incorporation of carbon in the protein complex and in the amino acids (Ref 7). Under certain conditions, ammonia nitrogen promotes the formation of the photosynthetic process. Nitrate nitrogen, however, always does so (Ref 8). Therefore, the authors have supposed that the nutrition of the plant with nitrate (oxidized and ammonia (reduced) nitrogen) essentially affects the formation of photosynthetic products (also of intermediates), as was proved for chlorophyll (Ref. 8). In

Card 1/4

The Effects of Different Nitrogen Forms on the
Composition of Labelled Photosynthetic Products in Maize and Phaseolus SOV/2o-122-4-32/57

order to clarify this question, leaves of 10-15 day old maize and phaseolus-plants were exposed in an atmosphere containing C¹⁴ for 1,5 and 10 minutes (method according to reference 9). The leaves were from plants which were cultivated either with nitrate - or ammonia nitrogen or without nitrogen. From the results in table 1 it is seen that the highest portion of radioactivity in the maize leaves is in the fraction soluble in alcohol. The alcohol-insoluble portion is barely 1-5% and increases with prolonged exposure. In the phaseolus, however, the insoluble portion is 24% of the total activity. This difference is due to the higher amount of proteins built up in the legumes, most of these proteins being insoluble in 80% alcohol. The highest amount of compounds which are insoluble in alcohol is found in the leaves of plants brought up without nitrogen, with an exposure of 5 and 10 minutes. Here, starch is produced in higher quantities (Refs 11, 12). From table 1 it is seen that the nitrogen forms exert no significant influence on the ratio of the radioactivity

Card 2/4

The Effects of Different Nitrogen Forms on the
Composition of Labelled Photosynthetic Products in Maize and Phaseolus SOV/2o-122-4-32/57

of all the compounds, soluble and insoluble in alcohol. The experimental results, however, show that the nutrition of plants with various nitrogen forms increases the radioactivity of the free amino acids. The findings further prove that the nutrition of plants with various nitrogen forms affects the method of carbon assimilation by producing distinct differences in the composition of labelled photosynthetic products. Further communications on character and cause of these differences will follow. There are 1 figure, 3 tables, and 17 references, 15 of which are Soviet.

"Assimilation and Distribution of C¹⁴ in Winter Wheat Kept at Various
Temperatures"

Sofia, Doklady Bolgarskoy Akademii Nauk, Vol 18, No 5, 1965, pp 257-260

Abstract: [English article] Essential changes occur in the structural state of the protoplasm and in the metabolism of winter wheat plants in the process of their hardening in autumn. It has been established that the hardened plants of winter wheat differ from the unhardened ones also by more stable chloroplasts (G. Salcheva, G. Samygin, Fiziologiya rasteniy, 10, 1960, 1). In connection with these changes of the chloroplasts with the process of hardening, it seemed useful to make a survey of photosynthesis and products in winter wheat kept at temperatures appropriate for the second stage of hardening (-3°, -5° C). Three tests were made with the frost-resistant variety No. 14 and the nonresistant variety No. 159. During the first two tests the plants were cultivated in winter, whereas during the third test they were cultivated at higher temperatures in spring. The tests show that under the influence of low temperatures (-3°, -5° C) there occurs a change in the ratio between the synthesized products in the process of photosynthesis, with an intensification of the synthesis of alcohol-insoluble compounds. These changes are more pronounced in the case of frost-resistant

Card 1/2

0922 0508

L 02152-67

ACC NR: AP6035985

variety No. 14, and this can be explained by the more profound changes occurring in it during the second stage of hardening. This variety differs from the nonresistant one in the greater content of labelled sugar when exposed to low temperatures. The nonresistant variety No. 159 shows a lower decrease in the intensity of assimilation at low temperatures. This paper was presented by Academician D. Yordanov on 20 November 1964. TITLE: Accumulation of biomass and protein nitrogen in Scenedesmus cells exposed to various forms of nitrogen

SOURCE: Bulgarska akademiya na naukite. Doklady, v. 19, no. 12, 1966, 1187-1190

TOPIC TAGS: algae, plant physiology, plant chemistry, altered gas atmosphere, nitrogen, photosynthesis, plant metabolism

ABSTRACT: This experiment was designed to trace the effect of nitrate, ammonia nitrogen, nitrite, and urea on the growth and biomass accumulation of Scenedesmus quadricauda 120. The culture was grown in Rou vessels at 26C, exposed to lamps for eight hours daily (3,500 lux) and supplied with a 1% CO₂-enriched air mixture. The culture medium lacked nitrogen (Chu) which was introduced after 16 hr (140 mg of nitrogen/liter) in the form of NaNO₃, NaNO₂, (NH₄)₂SO₄, (NH₂)₂CO. Samples were analyzed after six days. The quantity of absolutely dry biomass was determined by filtering a certain volume of suspension through a Seitz filter. The density of the

Card 1/3

UDC: none

ACC NR: AP7003867

suspension and pigment content were determined by the Lowry method. Tables 1—3 show some results of the experiment. The study demonstrated

(NH ₄) ₂ CO	4.23	3.17

that various forms of nitrogen have a specific effect on Scenedesmus metabolism. Ammonia nitrogen stimulates protein synthesis and the accumulation of dry matter, while inhibiting cell division. Greatest biomass yield resulted from the use of urea nitrogen followed by nitrate nitrogen. The smallest absolute biomass yield occurs when nitrite nitrogen is used. This substance inhibits culture vitality and development.

ANTENNAS

"Optimum Linear In-Phase Antennas with Continuous Current Distribution",
by I.F. Sokolov and D.Ya. Vakman, Radiotekhnika i Elektronika, No 1,
January 1958, pp 46-55.

Dolph (Proceedings IRE, 1946, Vol. 34, No 6, page 335) developed a method for calculating the optimum linear in-phase antennas, consisting of individual dipoles. This method is extended by the authors to include antennas with continuous distribution of current along the dipole. They derive and analysed formulas for the directivity patterns, for the distribution of the current amplitude, and for the efficiency.

TITLE: Optimum Linear In-Phase Antennas Having a Continuous Current Distribution (Optimal'nye lineynye sинфазныe antenny s nepreryvnym raspredeleniyem toka)

PERIODICAL: Radiotekhnika i Elektronika, 1958, Vol.III, Nr 1,
pp.46-55 (USSR)ABSTRACT: The optimum radiation pattern of a directional antenna, as defined by Dolph (Ref.1) is the pattern which, for a given width of the main beam, has a minimum level of the side lobes, or, alternatively, at a given level of the side lobes, gives a minimum width of the main lobe. The problem of designing this type of antenna was solved by Dolph by means of the Chebyshev polynomial and the width of the main beam of the radiation pattern at a level, r , is expressed by Eq.(1), where R is the relative level of the side lobes and n is the number of the equidistant radiators. The parameter u is defined by :

$$u = \frac{\pi d}{\lambda} \sin \theta , \quad (2)$$

Card 1/4

10)-1-5/16

Optimum Linear In-Phase Antenna Having a Continuous Current Distribution

where d is the distance between the radiators, λ is the wavelength and θ is the angle measured from the perpendicular of the radiator (see Fig.1). Eq.(1) can be modified to cover the case of a continuous antenna, which can be regarded as being constructed of an infinite number of radiators; the length of the antenna is D and if D is assumed to be a constant, the spacing between the radiators decreases to 0 as n tends to infinity. By introducing a new variable defined by:

$$v = \frac{\pi D}{\lambda} \sin \theta , \quad (3)$$

Eq.(1) can be expressed as Eq.(5), which can be solved with respect to r . The resulting solution is expressed by:

$$r = E(v) = \frac{ch \sqrt{\frac{2}{R - v^2}}}{R} \quad (6)$$

The equation was used to construct a number of radiation patterns for various R and these are shown in Figs.2. An

Card 2/4

100-1-5/18

Optimum Linear In-Phase Antenna Having a Continuous Current Distribution

attempt is made to evaluate the current distribution in the above optimum antenna. It is shown, however, (see Fig.4) that the current distribution is not physically realisable since the antenna should have considerable current jumps at its edges. An attempt is made, therefore, to determine the radiation patterns of the antenna in which the current distribution is a monotonically decreasing function, i.e., there are no sudden jumps at the edges. The radiation patterns of such antennas, referred to as the quasi-optimum antennas, is defined by Eq.(18). The resulting curves are shown by dashed lines in Figs.2. By comparing the curves for the optimum and the quasi-optimum antennas, it can be seen that the latter has a somewhat wider main lobe and a slightly higher first side lobe. The current distribution necessary to achieve the quasi-optimum radiation pattern can be found from Eq.(19). The equation can be solved approximately. The results shown in Fig.6 represent the current distribution calculated for various levels of the side lobes (from 20 to 60 db). From these

Card 3/4

100-1-5/10

Optimum Linear In-Phase Antenna Having a Continuous Current Distribution

curves it is seen that the quasi-optimum current distribution is governed by a smooth monotonic function. If the side lobe level is decreased, the slope of the current distribution curve is increased and the current amplitude at the edge of the antenna is reduced. Also the directivity coefficients of the optimum and quasi-optimum antenna were calculated as a function of D and R and these are shown in Figs. 7 and 8. There are 3 figures and 2 English and 3 Russian references.

ABSTRACT:

This is an estimation of the factors involved in the operational conditions which are valid for condensers in pulse-generating circuit elements. The qualification of condensers to operate under these conditions is determined. In order to judge the qualification of a condenser for a certain pulse circuit it is not necessary to investigate its properties in a wide frequency band, as long as the examination is limited to a first order approximation. It is sufficient to determine the permissible current at an equivalent frequency, which is dependent upon the pulse shape of the condenser. In this manner it is possible to find the requirements imposed upon condensers for arbitrary pulse-generating circuit elements of modulators. This is true in particular for tank capacitors. First the pulse shape in the condensers of the pulse circuits is investigated

Computation of the Equivalent Parameters for Estimating the Heat Balance in
the Condensers of Pulse Modulators

SOV/108-13-9-7/26

and then rms current, the reactive power and the equivalent frequency is calculated. Finally a sample problem is computed. There are 2 figures and 7 references, 6 of which are Soviet.

TITLE: Application of the Stationary Phase Principle to the
Evaluation of the Spectra of Radio Pulses

PERIODICAL: Radiotekhnika i elektronika, 1959, Vol 4, Nr 7,
pp 1124 - 1133 (USSR)

ABSTRACT: The method is based on the application of the following
formula (S.I. Bychkov - Ref 1 and N.I. Korman et al. -
Ref 2):

$$u(t) = Af(x)e^{-j[\omega_0 \tau x + K\Phi(x)]}$$

which represents a high-frequency pulse signal. The
parameters A , ω_0 and τ denote the amplitude, the
carrier frequency and duration of the pulse; $x = t/\tau$
is the normalised time, $f(x) < 1$ is a symmetrical
Gaussian-type envelope, K is the phase-modulation index,
which is equal to $2\pi\epsilon A\tau$, where ϵ is an electronically
caused frequency deviation; $\Phi(x) = \int_0^x f(x)dx$ describes

Card 1/3

SOV/109-4-7-6/25

Application of the Stationary Phase Principle to the Evaluation
of the Spectra of Radio Pulses

the law of the phase change. This can be represented by Eq (1). The spectrum of the pulse is given by:

$$G(\xi) = A\tau\xi \int_{-\infty}^{+\infty} e^{-jk\varphi(x) - \xi x} dx = 2A\tau\xi \int_0^{+\infty} \cos K[\varphi(x) - \xi x] dx \quad (2)$$

The sub-integral function in Eq (2) can be expanded into a Taylor series, such as is shown in Eq (5). The spectrum can then be represented by Eq (6). This can easily be evaluated by employing the tables of the Fresnel integrals. The resulting formula is not very accurate and it is necessary to employ an approximating function, which is in the form of Eq (8). In this case, the spectrum is given by Eq (10). For the region of $0 < \xi < 1$, where $\xi = 1/K(\omega - \omega_0)\tau$ represents the relative de-tuning, Eq (10) can approximately be represented by Eq (12). For the region of $\xi \geq 1$, the

of the Spectra of Radio Pulses

SOV/109-4-7-6/25

spectrum is given by Eq (20). The above formulae were employed to evaluate the spectra for a Gaussian pulse having an envelope of the type $f(x) = e^{-x^2}$. The results are plotted in Figure 3. The author expresses his gratitude to Ye.L. Feynberg for his interest and advice. TITLE: Signal Distortion in Delay Lines^b

PERIODICAL: Radiotekhnika i elektronika, 1960, Vol 5, Nr 4,
pp 621-632 (USSR)

ABSTRACT: Taking the solution for a distortionless delay line as the first approximation, asymptotic corrections are introduced for real lines with a large number of sections. Video pulses, high-frequency pulses and pulses with frequency-modulated carrier are considered, when the modulation^bspectra are narrow ("slowly-varying" envelopes) in comparison with the delay-line bandwidth. However, it is permitted for the carrier frequency to be close to the cut-off frequency of the line. There are 6 figures and 9 references, 5 of which are Soviet, 1 German, 2 English and 1 Russian translation from English.

Complex signals and the principle of ambiguity in radar (Slozhnyye signaly i printsip neopredelennosti v radiolokatsii) Moscow, Izd-vo "Sovetskoye radio", 65. 0303 p. illus., biblio., index. 6,800 copies printed.

TOPIC TAGS: radar signal analysis, radar observation, quantum mechanics, radar homing

PURPOSE AND COVERAGE: The book contains several problems on the theory of complex signals used in radar. It examines the properties of the functions of ambiguity of Woodward. In particular, it analyzes the radar principle of ambiguity and its role in observations and emphasizes the principle difference, peculiar to radar observations. Principle attention is devoted to the synthesis of radar signals according to the functions of ambiguity. It analyzes constructive methods of synthesis, optimum signal forms and other problems. The book is intended for engineers, aspirants and students of advanced courses of radiotechnical specialties.
