

News in Brief

SOV/32-25-8-28/44

alloys according to a series of standard samples. A spectrograph ISP-22 and an ac arc generator PS-39 were used. 4) The author reports on a method for localized spectrum analysis of steels and welded seams for the determination of phosphorus. The distribution of P was investigated in thin layers (up to 0.02 mm) of metals and welding seams by the use of a DG-1 generator and a quartz spectrograph and the phosphorus contents of microscopic inclusions and thin coatings were investigated. 5) The author determines calcium oxide and ferrous oxide in slags of electric furnaces in which the slag sample (0.2 g) was wetted with a saturated aqueous copper sulfate solution (2 ml) subsequently dried and put in the craters of two arc carbon electrodes. Spectrograph ISP-22 and generator DG-1 were used. 6) The author analyzed magnesite and magnesitic refractory substances by mixing the sample with carbon and barium nitrate (1:2:1) and evaporating it in the crater of a carbon electrode in an ac arc. A spectrograph ISP-22 was used. The use of this method was introduced at the Plant "Magnezit", Kuznetakiy metallurgicheskij kombinat (Kuznetsk Metallurgical Kombinat) and Zaporozhskiy zavod ogneuporov (Zaporozh'ye Plant of Refractory Materials). 7) The authors apply a spectrum method for the determination of phosphorus

pentoxide in zirconium dioxide. The determination takes only 2 hours. 20 mg of the sample mixed with carbon (1:1) is put into the carbon electrode and the spectrum lines are measured with a spectrograph ISP-28. 8) The authors, working in the laboratoriya instituta (Institute Laboratory) report the preparation of standard samples from technical Ti for the determination of hydrogen by the spectrum method. The article contains a description of the preparation method and the determination results according to different methods of the hydrogen in standard samples (Table). The difference is maximum relative  $\pm 13.5\%$ . 9) The author reports on a simple spectrum method for the determination of small quantities of Ba and Mn in calcium chloride water of high mineral contents. He used a spectrograph ISP-22, microphotometer MF-2 and standard samples. There are 1 figure and 1 table.

AUTHOR: Veselovskaya, I.M. 32-24-6-16/44

TITLE: Operating Test of the FES-1 Styrometer  
(Op'yub raboty fotoelektricheskogo stilometra FES -1)

PERIODICAL: Zavodskaya Laboratoriya, 1958, Vol 24, Nr 6, pp 709-710 (USSR)

ABSTRACT: Several investigations of the electric and optical part of the apparatus were carried out in cooperation with T.V. Kovalenko (TaNICHM), on which occasion the photometrical error in the light arc regime on the line Fe 4957.3 Å was determined. It was found that in the case of the revolving system the reproducibility error amounted to 1.64%, whereas without revolution it amounted to only 0.98%, so that the revolving system was eliminated. It was shown by experiment that it is possible to carry out analyses of chromium and manganese with an accuracy of up to some hundredth parts of a %, on which occasion the importance of the dimensions of operational- and auxiliary discharge distances was recognized. Seven seconds was found to be the optimal duration of preliminary irradiation; by longer exposure it was possible to improve reproducibility, and for low chromium- and manganese concentrations a light-arc regime was found to be of greater advantage. For the determina-

tion of chromium, the triplet 5204-5206-5208 Å and the line group 4254, 4274 and 4289 Å were found to be the most sensitive, but the sensitivity of the analysis decreases in the case of higher concentrations. For the determination of manganese the line 4823 Å was selected. It was found that the not split-up light beam can be considered to be a stable internal standard because also considerable changes of composition exercise no influence upon its intensity. A period of five minutes is mentioned for the analysis if determination is carried out twice, in which case 96% of the determinations carried out were within the permitted error limits. Several disadvantages of the apparatus are mentioned, but in conclusion it is said that, compared to the visual stylometer, greater accuracy and a more rapid analysis is rendered possible. There are 1 figures and 2 tables.

Orig Pub : S. kh. Sibiri, 1957, No 10, 33-37

Abstract : Cross-breeding, selection and station trials were carried out at the West Siberian Vegetable Experimental Station during 1950-1956. The fast ripening forms of watermelons - Tuvin'skiy mestnyy, Arikara, Hybrid 97 and others were differentiated. A new variety of watermelon - Sibirynk - produced on an average for 3 years a crop of 228 centners/ha of ripe fruit, and Stoks variety - 121 centners/ha. Breeding watermelon hybrids on pumpkin stock heightened

the fast ripening, increased the large size and the flavor qualities of the fruit before the 4th generation. The muskmelon varieties studied, were divided into three groups according to fast maturing. Hybrid forms from crossing varieties of different degrees of fast ripening, reduced their vegetation period, and increased dry matter content and fertility upon being grafted at cotyledon stage on pumpkin stock. In the variety trials the hybrid varieties produced a yield of 150-300 centners/ha. -- B.S. Shmal'ko

Sedimentary Rocks

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 127, Nr 3, pp 627 - 629  
(USSR)

ABSTRACT: Metasomatism of potassium, sodium, magnesium, iron, and silicate is widespread in pre-Cambrian rocks and was thoroughly investigated by several scientists (Refs 3,6,9, etc). It took place much later than the formation of the rocks transformed by it. A survey of publications (Refs 4,7) shows that potassium metasomatism ("microclinization", Figs 1a, b) is most widely spread, sodium metasomatism, however, is comparatively rare. This is true of the two last-mentioned types of metasomatism of the crystalline basis. The effect of these two metasomatoses on the old masses of the sedimentary cover of the Russian Platform was investigated in the present paper. In the old masses of the so-called Bavlinskaya Suite of the Volga-Ural region feldspathization was found to be widespread. The lower Bavlinskiye formations (Ref 1) are divided into the Kaltinskaya, Serafimovskaya, and

Card 1/3

New Data on Secondary Feldspars in Upper Proterozoic SOV/20-127-3-43/71  
Sedimentary Rocks

Leonidovskaya Suites. They are discordantly overlain by horizontal upper Bavlinskiye sediments (Lower Cambrian, Ref 1). The complete depth of the lower Bavlinskiye formations amounts to 800 m; they are situated at a depth of about 2,000 and 3,000 m. They are slightly metamorphosed, bearing dikes of gabbro diabases. A number of newly-formed feldspars were found in the two first-mentioned suites. The types of their sandy and aleuritic rocks are described (Figs 1,2). The lower Bavlinskiye sediments mentioned last (the two first-mentioned suites) belong to the Upper Proterozoic-Riffean, i.e. they are about 685 - 868 million years old (Ref 2). There was a continental break after their formation at the end of the Upper Proterozoic during which the deposits mentioned were dislocated. The dikes intruded probably at that time. It is possible that the K- and Na metasomatoses took place during this period. The absolute age of microcline in the pre-Cambrian microclinized granite-gneisses amounts to 700 - 800 million years (according to an oral information by A. I. Tugarinov). Thus, the two types of metasomatism took

Card 2/3

Sedimentary Rocks

place after the Upper Proterozoic folding and belong to the period of Baykal folds. The solutions rich in K and Na ascended in the breaks of the basis. Z. P. Ivanova directed the investigations. There are 2 figures and 11 references, 8 of which are Soviet.

On the Stratigraphic Subdivision and the Formation Stages of  
Pre-Devonian Deposits in the Central and Eastern Regions of  
the Russian Platform

## PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 128, Nr 4, pp 800 - 803  
(USSR)

## ABSTRACT:

The above deposits became interesting since petroleum was found in them. They contain Upper Proterozoic and Lower Cambrian formations in the sedimentary cover of the part of the platform mentioned above. More recent sediments: Upper Cambrian and Ordovician occur in the central regions of the platform and strike in a northwesterly direction. Only the two older ones (more than 3000 m thick) are discussed in the present paper. Quartzite sandstones (analogues of the Shokshinskiye) are the oldest of the platform formations investigated here. They rest directly upon the basement in Yulovo-Ishim and Yelshanka. They were identified by the authors as the Yulovo-Ishimskaya suite of "Iotnium". The deposits known as "Nizhne-Bavlinskiye" in the east, as Kaverinskaya and Serdobskaya

Card 1/3

On the Stratigraphic Subdivision and the Formation  
Stages of Pre-Devonian Deposits in the Central and  
Eastern Regions of the Russian Platform

SCV/2C-128-4-45/65

series in the central part lie stratigraphically higher above a disconformity and an angular unconformity (Refs 5,8). In the Nizhne-Bavlinskiye deposits the Kaltasinskaya- (316 m thick) and Serafimovskaya suites (450 m thick) and their time equivalent, the Serdobskaya series, are divided into lower and upper strata corresponding to the sedimentation half-cycles. In several cross sections the above suites are intruded by gabbro and diabase. Figure 1 shows the occurrence of the suites mentioned. A thick (more than 700 m) sandstone body classified by the authors as the Leonidovskaya suite (Ref 2) rests upon the Serafimovskaya suite. The Riffian formations are transgressively overlain by Lower Cambrian sediments with an angular unconformity and a stratigraphic disconformity. This body is most probably synchronous with the Volynskiy (volcanogenic) complex of the western part of the platform (according to Ye. P. Bruns, Ref 1). The Lower Cambrian (Verkhne-Bavlinskiye) deposits in the eastern regions of the platform consist of 2 complete sedimentation cycles. Table 1 gives a stratigraphic section of the pre-Devonian deposits. The authors identified

Card 2/3

On the Stratigraphic Subdivision and the Formation  
Stages of Pre-Devonian Deposits in the Central and  
Eastern Regions of the Russian Platform

SOV/2C-128-4-45/65

several time units in the latter according to the stratification peculiarities of the old platform sediments: (1) Yulovo-Ishimskaya suite of "Iotnium". (2) Riffian deposits, and (3) Lower Cambrian with decreasing angles of inclination (up to  $30^{\circ}$ ,  $10-17^{\circ}$ ,  $0-9^{\circ}$ , respectively). The rocks of individual structural stages belong to different zones with respect to the degree of deformation (Ref's 4,6). Figure 2 shows the micro-photographies of the rocks of the "Iotnium" age, figure 3 those of the Riffian age. There are 2 figures, 1 table, and 8 Soviet references.

pp 1085 - 1088 (USSR)

ABSTRACT:

The bore-hole mentioned in the title came upon metamorphic paleozoic rocks at a depth of 2566 - 2336 m. The authors describe types of these paleozoic rocks and of the above lying slightly altered Cretaceous sediments (depth 2336-2060 m) on the results of this and four other bore-holes (Fig 1). A part of the "buried Hercynids" (Ref 3) which is an old paleozoic mountain area that stretches to the east as well as to the west, was everywhere discovered below the Lower Cretaceous. I. Rock-types of the metamorphic Carboniferous. The authors were able to determine the age of the paleozoic rocks as Lower Carboniferous. 1) Cataclastic conglomerates.

Card 1 / 3

Formation and Variation Stages of Terrigenous Rocks SOV/20-123-6-35/50  
Illustrated by the Investigation of the Novo-Minskaya Well (The Near-Kuban' Lowland)

2) Cataclastic various-grained quartzite sandstones. 3) Carbonaceous sericite-schists. 4) Sericite-quartz-schists. 5) Glauconite-siderite-rocks. 6) Siderite-clay-rocks. 7) Quartz-, calcite-more rare chlorite veins. Table 1 shows the thickness of the most abundant rocks. II. Rock-types of the Lower Cretaceous. 1) Neocom rocks (depths 2336-2321 m): a) in the upper part dark-grey, almost black carbonaceous schists. b) in the lower part, sandstones of various grain size, mostly fine grained. 2) In the higher region (depth 2321-2060 m) lie rocks of the Lower Albian: a) grey quartz-glaucous aleurolites. b) quartz-glaucous sandstones. A bituminous content was discovered only in the black schists of the Carboniferous. (3). The bituminous content is spread and does not correspond to that of the oil region. In all Cretaceous rocks the bituminous content fluctuates between 0.05 and 0.156. These were oily and intermediate types and in single cases types similar to those of the oil regions. (Fig 2). The authors come to the following results according to the above mentioned facts:

I. The paleozoic rocks are altered until the stage of "meta-

Illustrated by the Investigation of the Novo-Minskaya Well (The Near-Kuban' Lowland)

SOV/20-123-6-35/50  
genesis" (beginning metamorphism) (Ref 1). II. The metamorphism observed in the Novo-Minskaya bore-hole has a regional spreading. The authors believe that all stages of the epigenesis and of the early metamorphism are of a regional importance. III. These rocks are almost completely enriched with quartz: secondary quartz occurs in the cement, the effusives are silicified, and many quartz veins occur. IV. The rocks of the Lower Cretaceous are altered as all indications show until the stage of beginning -"epigenesis" (Ref 1). Compactness here is, however, higher than that mentioned for the rocks in this zone. A. L. Yanshin, Academician, assisted in this work. There are 2 figures, 1 table and 3 Soviet references.

TITLE: The Proterozoic Rocks of the Eastern Slope of the Voronezh Massif (Proterozoyskiye porody vostochnogo sklona Voronezhskogo massiva)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 121, Nr 5, pp. 893-896 (USSR)

ABSTRACT: Proterozoic rocks were found in the vicinity of the massif, viz. in 11 bore holes. They are embedded in a depth of from 145 to 2170 m. Various symptoms indicate that the concerned area formed a peneplain during the sedimentation of the Devonian Deposits. The Eastern slope referred to in the title has been formed at the beginning of the Devonian time. The Pre-Cambrian Rocks descend eastwards, not evenly bedded, however, but in steps. 2 steps are investigated. It may be easily assumed that these steps are accompanied by faults in the foundation. This assumption agrees well with the data obtained from electrical investigations by means of which "elevations" were uncovered in the foundation rock. From the following descriptions of the rock proceeds that intrusions of different

Card 1/3

The Proterozoic Rocks of the Eastern Slope of  
the Voronezh Massif

SOV/20-121-5-35/50

ages are concerned. A north-east orientation both of the steps and of the intrusions indicates an affiliation of the latter with the deep faults of the foundation. A description of the rock types from the above mentioned bore holes is given. Figure 3 shows their distribution. Concluding, the age of these rocks is discussed: they date from the Lower Proterozoic time, Taratashskaya Suite (Refs 6,1). It is correlated with the Saksaganskaya series of Ukrainia (Ukraina), the Carelian formations of Carelia (Kareliya) and the Huron (Guron) of America (Biotite-tourmaline- and pyroxene-amphibole slate). The age of the granite gneiss containing tourmaline is hard to determine. They are either Neo-Archeozoic or Proterozoic. All rocks investigated here are doubtless of sedimentary origin. They are radically metamorphosed loamy and particularly carbonate rocks amongst which are also intermediary inter-Aleurolite sandstones and slates. Concluding, the tourmaline of that area has been mineralogically described. There are 3 figures and 7 references, 6 of which are Soviet.

Condensation reaction of *py*-indolesaldehydes with malonic acid and cyanoacetic ester. V. M. Rodionov and T. K. Veselovskaya (D. I. Mendeleev Chem.-Technol. Inst., Moscow). Zhur. Obshch. Khim. (J. Gen. Chem.) 20, 2302-12 (1950).—The Rodionov method of synthesis of  $\beta$ -amino acids (C.A. 31, 1257) cannot be used for  $\beta$ -amino acids of indole; unsat'd. acids are formed. Me groups in indole affect the ease of condensation with malonic acid: Me in the 2-position lowers the aldehyde activity, while 1-Me raises it. Addn. over 1 hr. of 125 g.  $\text{Me}_2\text{SO}_4$  to 28.1 g. 3-indolecarboxaldehyde (I) and 47.7 g. NaOH in 750 ml.  $\text{H}_2\text{O}$ , shaking 4 hrs., and letting stand overnight gave 23.0 g. 1-methyl-3-indolecarboxaldehyde (II), m. 69-70° (cf. Wieland, et al., C.A. 29, 781<sup>1</sup>), while the mother liquor gave an addnl. 2.6 g. 3-indolecarboxaldehyde, m. 100-2°. 2-Methyl-3-indolecarboxaldehyde (III), m. 188-200°, by cyclization of  $\text{MeC}_6\text{H}_4\text{NNHPh}$  with  $\text{ZnCl}_2$  in cumene, and introduction of  $\text{CHO}$  according to Boyd and Robson (C.A. 29, 8044<sup>1</sup>) into 2-methylindole, m. 143-4°. Methylation of III with  $\text{Me}_2\text{SO}_4$  in aq. KOH at 0° gave 70% 1,2-dimethyl-3-indolecarboxaldehyde, m. 128-30° (from EtOH). Heating 2 g. I, 1.6 g. malonic acid, and 5 ml. 7% aq.  $\text{NH}_3$  on a steam bath 5 or 17 hrs. gave largely unreacted I and malonic acid; a minute amt. of unidentified acid was also obtained. With heating, II in 5 hrs. gave (from 8 g. II) 4.15 g. green solid, m. 182-3°, identified as (1-methyl-3-indolylmethylene)-

malonic acid,  $\text{C}_{11}\text{H}_{10}\text{O}_4\text{N}$  (IV), which heated with  $\text{PhNMes}_2$  to 160° over 1 hr., gave  $\text{CO}_2$  and 1-methyl-3-indole-acrylic acid, m. 103-4°, a very small amt. of possibly 1-methyl-3-indoleindole, m. 73-4°, also formed; thus, boiled with 10% KOH gave a solid, m. 98-9°. The reaction of malonic acid with III did not proceed under all conditions tried. 1,2-Dimethyl-3-indolecarboxaldehyde (V) was also unchanged and only a trace of a mixt. of 2 acids, m. 156-9° and m. 154-6°, was secured, possibly 1,2-dimethyl-3-indole-acrylic and (1,2-dimethyl-3-indolylmethylene)malonic acids. Heating 1.5 g. I, 3 g. malonic acid, 5 ml. pyridine, and 3 drops piperidine 40 hrs. at 38-40° gave after treatment with dil. HCl and extn. with EtOH, 0.3 g. I, and 31.6% 3-indoleacrylic acid, m. 103 0°. With II were obtained 0.2 g. 1-methyl-3-indoleacrylic acid, m. 103-4° (from EtOH), and 0.7 g. IV, m. 182-3°. III and V did not react, except for possible trace apts. 1 (0.75 g.), 0.85 g.  $\text{EtO}_2\text{CH}_2\text{CN}$ , 10 ml. EtOH, and 3 drops piperidine let stand 48 hrs. gave 91.9%  $\text{Et}(\text{c}-\text{cyano-3-indole})\text{Ac}$  (VI), m. 164-5°. II similarly gave 63.7% of the 1-Me deriv. of VI, m. 149-50°. III gave 26.1% 2-Me deriv. of VI, m. 219-10°, and V gave 7% 1,2-di-Me deriv., m. 129-30°. G. M. K.

TITLE: Electrochemical and Photoelectrochemical Behavior of the  
Silicon Electrode

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 133, No. 2,  
pp. 392 - 395

TEXT: The authors investigated monocrystalline silicon of the n- and p-type with  $p = 1 \text{ ohm.cm}$  and crystallographic (111) orientation of the surface. A cinematographic incandescent lamp served as light source ( $\sim 10^{-1} \text{ cal/cm}^2.\text{sec}$ ). The silicon surface was etched in hot KOH or in HF + HNO<sub>3</sub>, or ground. Fig. 1 shows the dissolution of Si under hydrogen separation in KOH solutions of 0.1 - 10 N. The time change in potential occurring at the same time is the same for n- and p-Si, and depends on how the surface has been treated. Fig. 2 shows the curves of the anodic polarization for both types immediately after plunging into the solution and after the stable state has been reached. There is no essential

difference between the two types of silicon apart from the fact that the maximum potential of the anodic curve is 200 mv more positive for the p-type than for n-Si. The photogalvanic activity  $\Delta V$  of the system is changed by etching. In the case of p-Si  $\Delta V^c$  rises from zero to the constant value of 600 mv; in the case of n-Si  $\Delta V^c$  becomes not more than 10-15 mv (Fig. 3). Oxidation of the surface both by means of anodic polarization and by chemical etching or introduction of oxygen into the solution exerts an influence upon the photoelectric effect; in the case of n-Si  $\Delta V^c$  is increased to 50-100 mv and  $\Delta V$  reduced in p-Si to 200-400 mv. After the dissolution of the oxide film the photoelectric effect is increased in p-Si and decreases with n-Si (Fig. 4). The difference of  $\Delta V^c$  for p- and n-Si in the presence of an electric field is caused by the fact that in the dissolution the surface of p-Si approaches the n-type, whereas oxidation acts in the opposite direction. Though the measured static potentials are the same for both types, the distribution of the change in potential is different at the interface of silicon - solution. The etching off of the mechanically defective layer leads to the increase of  $\Delta V^c$  in p-Si. Light acts mainly upon the space charge which can be also seen from the practically unchanged

hydrogen separation in the case of an exposure to light. The independence of the rate of irreversible dissolution of silicon in alkali of its type is due to the action of two conjugate reactions of oxidation and reduction. There are 4 figures and 7 references: 1 Soviet, 5 British, and 1 German.
