

*OR*

Influence of the rate of deformation on the cold brittleness of steel. II. P. F. Vitman and V. A. Stepanov. *J. Tech. Phys.* (U. S. S. R.) 9, 1985 90 (1939); cf. C. A. 34, 1957. Notched cylinders of steel (C0.25%) were broken in bending at different speeds of the impact of a double knife. The upper crit. temp.  $T$  of the cold brittleness rose from  $-70$  to  $36^{\circ}$ , and the lower crit. temp. from  $-115$  to  $-5^{\circ}$ , when the speed  $V$  increased from  $6.10^{-4}$  to  $83$  m./sec.,  $\ln \log v = A - (B/T)$ ,  $A$  and  $B$  being const. The effect of the notch is the stronger the higher the speed. J. J. Bikerman

ASLIB-LA METALLURGICAL LITERATURE CLASSIFICATION

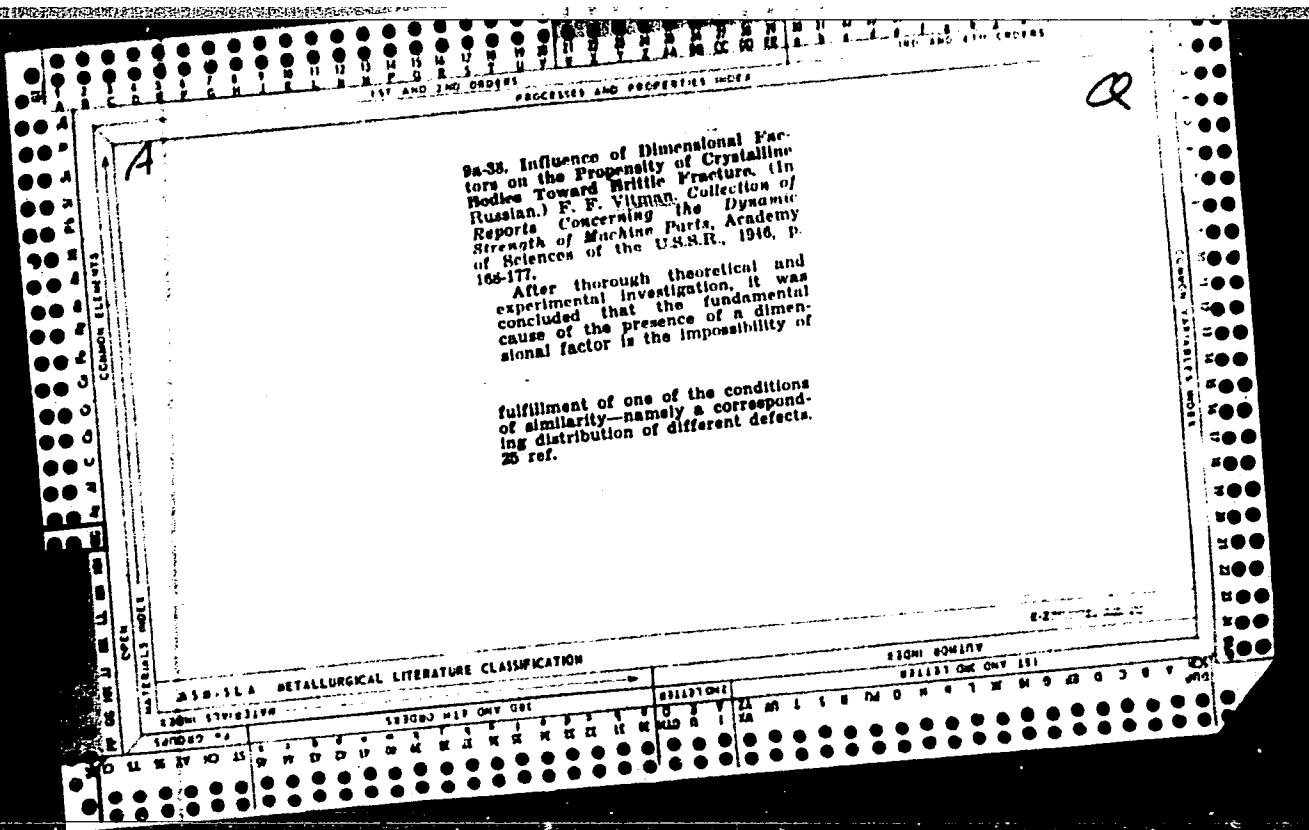

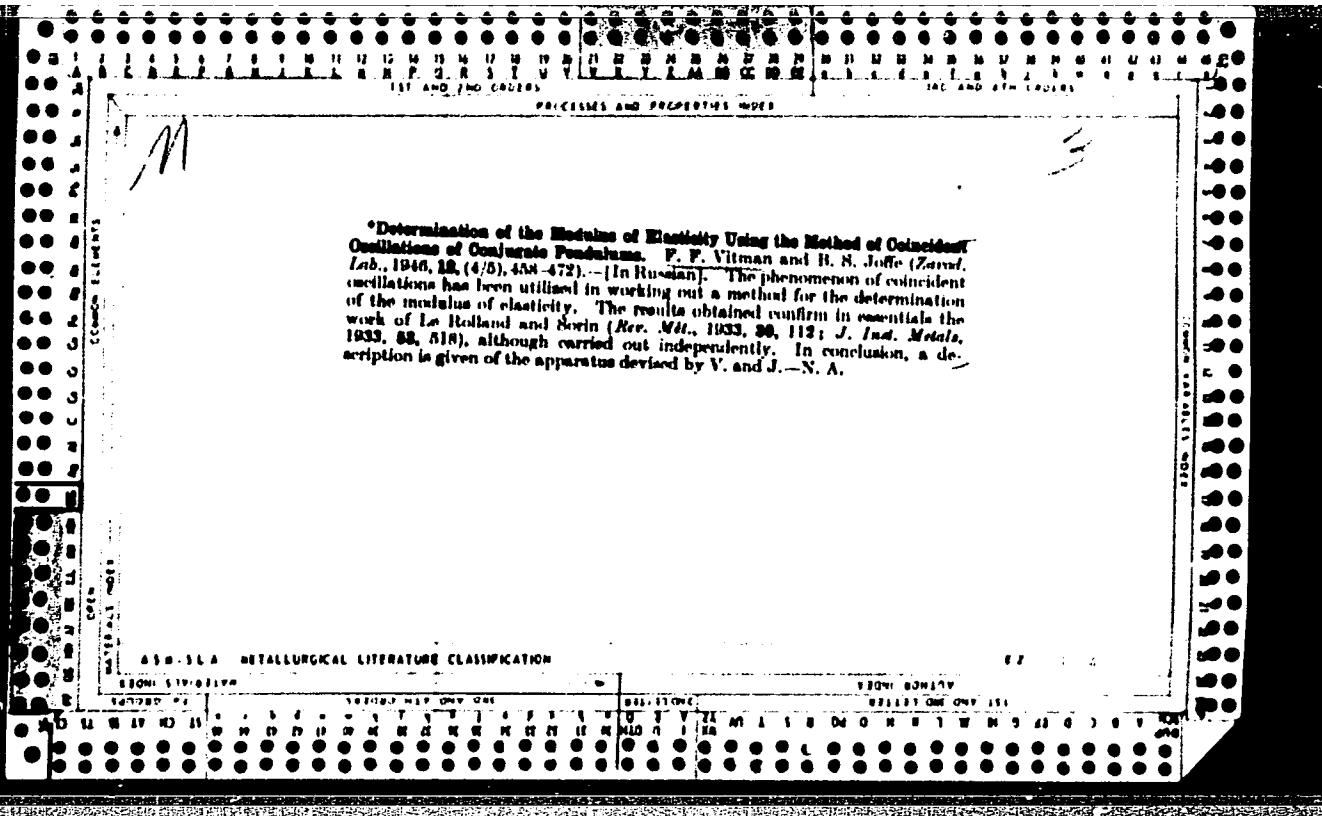

**On a Method for the Study of the Mechanical Properties of Chromium Coatings.** E. F. Vitman and N. N. Davidenkov (*Zavod. Lab.*, 1945, 11, (9), 844-852).—[In Russian]. Describes a method for the determination of the normal elastic modulus of chromium in coatings, the elastic limit in tension, the adhesion of the coatings to the basis metal, and their resistance to cutting action.—N. A.

Application of Cyclic Impression to the Study of the Rate of Resistance to Deformation of Metals. (In Russian.) F. E. Vitman and others. Zavodskaya Laboratoriya (Factory Laboratory), v. 13, July 1948, p. 579-594.

Proposes a new method of determining the characteristic mechanical strength of metal. This method consists of the analysis of the field of deformation induced by a cone and of the selection of criteria of the rate of deformation. The theoretical bases are explained, and the procedure is discussed. Mathematical computations (24 formulas) of obtained data are given. 12 ref.

8273. Resistance to deformation of metals at velocities  $10^3$  to  $10^4$  m/sec. III. R. E. VITMAN AND N. A. ZLATIN. *J. Tekh. Metal.*, USSR, 20, 1267-72 (Oct., 1950) *In Russian*.  
For Pt II, see Abstr. 3713 (1949). Results of experiments with Cu, Zn, Al and Sn again confirmed the existence, in the range covered by the tests of variations of temperature and velocities of 3 separate ranges of variation of these parameters within each of which one definite mechanism for the influence of velocity on the resistance to plastic deformation predominates. In post-recrystallization conditions of deformation the tests fully reproduced the conditions previously found in experiments with Pb and corroborated the equation representing them, viz.  $H_A = H_{A0}(t/t_0)^{1/2}$ . On the other hand, in pre-recrystallization deformation of the soft metals brought out to satisfy the expression previously found for it, viz.  $H_A = M(t \exp M/T)^2$ . The results of this test series, just as the previous experiments with Pb, showed that the link on the characteristics of the deformation resistance v. speed at temperatures exceeding the recrystallization temperature corresponds for all the metals to approximately the same resistance value independent of speed and temperature. R. E. ARAKS

**ПОДСКАЗКА:** This book is intended for construction engineers, technologists, physi-  
 cists and other persons interested in the strength of materials.

**ОБРАЗЕЦ:** This collection of articles was compiled by the Odzhalynsky Institute of Strength of Materials of the USSR (Institute of Physical and Mathematical Sciences) and the Pistoia Scientific Institute of Applied Physics, Academy of Sciences, USSR (Institute of Applied Physics), in commemoration of the 30th birthday of Nikolay Nikolaevich Polikarpovich (Institute of Strength of Materials of the USSR (Institute of Physical and Mathematical Sciences)) at the Odzhalynsky Institute of Strength of Materials of the USSR (Institute of Applied Physics, Academy of Sciences, USSR). Nikolay Nikolaevich Polikarpovich was born on 10 May 1901 in the village of Pistoia, Italy. He graduated from the University of Milan in 1924. In 1925 he became a member of the Italian Academy of Sciences. In 1927 he became a founder of the Odzhalynsky Institute of Strength of Materials of the USSR (Institute of Strength of Materials of the USSR (Institute of Physical and Mathematical Sciences)). He was elected a corresponding member of the USSR Academy of Sciences in 1941. In 1945 he became a member of the Order of the Red Banner of Labor (1945) and the Order of the Lenin Prize (1955). In 1955 he became a member of the Order of the Red Banner of the Soviet Union (1955). The article deals with the strength of materials, hydrogen embrittlement, cold brittleness, plasticity, temper brittleness, hydrogen embrittlement, cold brittleness, influence of deformation speed on the mechanical properties of materials, fatigue of metals and some salts, various personalities, and mechanical properties of steel. The author, S. I. S. V. Friedman, and Yu. A. Torts, Effect of Site of Test Place on The Strength Under Repeated Stress.

Shevandin)

PERIODICAL:

Zavodskaya laboratoriya, 1959, Vol 25, Nr 7, p 896 (USSR)

ABSTRACT:

This is an obituary written on the occasion of the death of the scientist mentioned in the title. Shevandin was one of the leading scientists in the field of material mechanics; he became famous for his investigations of the nature of destruction by brittleness and the phenomena of destruction by brittleness of metals at low temperatures carried out at the Fiziko-tehnicheskiy institut (Physical and Technical Institute). After 1945 the deceased dealt with the problems of cold-shortness of ferrous metals which are of great importance in ship-building. Ye. M. Shevandin published two manuals on the mechanical properties of metals as well as

AUTHORS: Boguslavskiy, I. A., Vitman, F. F., and Pukh, V. P.

TITLE: Increase of the strength of thin glass

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 138, no. 5, 1961, 1059-1061

TEXT: Two methods have recently been proposed for improving the strength of glass: hardening and chemical etching. Hardening and subsequent etching have also been studied in detail. However, these methods are only suitable for glass having a thickness of more than 5 mm. The strength of glass 1.5-3.0 mm thick is not considerably improved by hardening in air. Etching of such glass, however, raises their average strength to 50-60 kg/cm<sup>2</sup>. These values are only slightly lower than those obtained for thick glass. The authors present the results of experiments made with glass specimens having dimensions of 80-90 mm and a thickness of 1.5, 3.0, and 5.0 mm. The specimens had non-processed and mechanically polished surfaces, and were treated a) thermochemically, b) by etching with hydrofluoric acid solution, and c) by applying both methods successively. In the first method, the specimens were placed perpendicularly in a tem-

Card 1/5

Increase of the strength of 25110

S/020/61/158/005/010/025  
L'04/B205

tering furnace and heated to a temperature slightly above that at which the glass softens. After 2-3 min the specimens were cooled in silicone oil and air. In the second method, a layer of 0.1 mm was removed from the surface of the specimens by etching in 20% hydrofluoric acid. The third method combines the first two procedures. The results of the tests are shown in figs. 1 and 2. The combined method (thermochemical treatment followed by etching) is shown to furnish the best results. It ensures a strength of 70-80 kg/cm<sup>2</sup>. Optimum results were obtained for 1.5-mm glass whose surface had not been processed and which had a relatively high initial strength. The factors increasing the strength of glass are still unknown. It is believed that strength-reducing flaws in the surface layer are eliminated by etching or by thermochemical treatment. The rapid cooling in a liquid organo-silicon medium is likely to change the distribution of hardening strains across the thickness of the glass specimen which, in turn, gives rise to strong compressing forces in the surface layer. On the other hand, it is also necessary to take into account the effect of the hydrophobic layer which is formed on the surface of the glass specimen while being cooled in silicone oil, as well as the interaction of the strongly heated glass with the organo-silicon compounds. By

using liquids that allowed the glass to be cooled more rapidly, it was possible to reach a bending strength of 100-120 kg/mm<sup>2</sup> for glass of 5 mm thickness. The bending strength could be raised up to 150 kg/mm<sup>2</sup> by reducing the thickness of the glass. There are 2 figures and 8 Soviet-bloc references.

TITLE: Residual stresses in glasses quenched in liquids

PERIODICAL: Fizika tverdogo tela, v. 4, no. 8, 1962, 2151-2159

TEXT: Complete diagrams plotted by the strip and the plate methods, are given for the residual stresses in glasses of 1.5, 3, 5, 8, and 12 mm thickness treated by the process of S. I. Sil'vestrovich and I. A. Boguslavskiy (DAN SSSR, 129, no. 6, 1362, 1959; author's certificate 132374, 1959). Mechanical measurements of residual stresses clearly proved the advantages of glass quenching in liquids, indicating that this method of quenching ought to be further developed. Thin glasses poorly quenched in air blasts have the same quenching stresses, after a second liquid quenching, as thick glasses after a quenching of 3-4 por./cm. Considerably higher compressive stresses occur on the surface of thick liquid-quenched glasses. They are higher than when the glasses are quenched in air blasts for the same period. Since under these conditions the optical stress measurement is not reliable it should be replaced by

Card 1/2

Residual stresses in glasses ...

S/181/62/004/008/C17/041  
B125/B102

a mechanical measurement of the residual stress. Quenching causes higher stresses in square glass plates than in prismatic glass strips. The stresses in quenched glasses can be better determined by mechanically measuring the residual stresses in plates (biaxial state of stress) than by the customary method using specimens in the form of strip. There are 8 figures and 1 table.

TITLE: Glass hardening

PERIODICAL: Fizika tverdogo tela, v. 4, no. 8, 1962, 2160-2168

TEXT: Glasses were tested after being hardened in the following ways: (1) by quenching in polysiloxane liquids and in mineral oils; (2) by etching in hydrofluoric solutions, and (3) by quenching with subsequent etching. In each case the specimens were of vertically drawn glass, measuring 80 mm square and of 1.5, 3.0, and 5.0 mm thickness, with both natural and mechanically polished surfaces. The strength of the glass plates 1.5 to 3.0 mm thick was found to be only slightly increased by quenching in air blasts. The strength of those 5 to 6 mm thick can be increased, by quenching in organosilicon oils or in mineral oils, from 10-20 kg/mm<sup>2</sup> up to 30-80 kg/mm<sup>2</sup>. By subsequent etching in hydrofluoric solutions it can be to 60 to 125 kg/mm<sup>2</sup>. By this method of hardening the strength of the glass plates 1.5-3.0 mm thick could be increased to the unprecedented level of 50 kg/mm<sup>2</sup>. Glass hardening by quenching in air

Card 1/2

Glass hardening

blasts and liquids is due to compressive stresses generated in the surface and largely to physical changes produced in the surface layer of the glass. The contribution of these physical changes to hardening is the greater the more rapidly the gas is cooled. This two-stage hardening process is well suited for the commercial production of large glasses and for various engineering purposes. There are 3 figures and 1 table.

TITLE: A problem of the collision of plastic bodies

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 146, no. 2, 1962, 337 - 339

TEXT: The collision of a plastic solid of revolution (2) with a plastic semispace (1) is studied on the assumption that the axis and the velocity vector of (2) coincide with the surface normal to the semispace. The problem is solved in terms of the theory of dimensions (L. I. Sedov, Metody podobiya i razmernosti v mekhanike - Methods of similitude and dimensions in mechanics, M., 1957). The parameters of the shock adiabate are used to allow for the compressibility of the two bodies, a linear relation being assumed to exist between the velocity D of the shock wave and the mass velocity u behind the wave front. The pressure behind the wave front is then  $p = \rho_0 Du = \rho_0 (a + bu)u$ , where a and b are constants of the material, determined from the shock adiabate, and  $\rho_0$  is the density at standard pressure. The process is described by the impact velocity  $v_0$ , the

Card 1/4

S/020/62/146/002/005/013

A problem of the collision...

dynamic hardnesses  $H_1$  and  $H_2$ , the densities  $\rho_{01}$  and  $\rho_{02}$  at standard pressure, the cohesion energies  $Q_1$  and  $Q_2$ , the compressibility characteristics  $a_1$ ,  $a_2$ ,  $b_1$  and  $b_2$ , the diameter  $d_0$  of the characteristic cross section, the characteristic length  $l_0$  of the body (2), and by the depth  $L_k$  of the indent resulting from the collision in (1). In accordance with the  $\Pi$ -theorem of the theory of dimensions, the 15 parameters stated above may be replaced by 12 dimensionless combinations. An implicit equation for the process under consideration can be derived from the functional relation between these combinations:

$$\frac{L_k}{l_0} = f \left( \frac{\rho_{01}v_0^2}{H_1}, \frac{H_2}{H_1}, \frac{\rho_{02}}{\rho_{01}}, k_0, \frac{l_0}{d_0}, a_1 \sqrt{\frac{\rho_{01}}{H_1}}, \frac{\rho_{02}a_2}{\sqrt{\rho_{01}H_1}}, b_1, \frac{\rho_{02}b_2}{\rho_{01}}, \frac{\rho_{01}Q_1}{H_1}, \frac{Q_2}{Q_1} \right). \quad (2),$$

which, according to Sedov, can be reduced to

Card 2/4

S/020/62/146/002/005/013

B104/B108

A problem of the collision...

$$\frac{L_x}{l_0} = F \left( \frac{p_{01}v_0^2}{H_1}, \frac{H_2}{H_1}, \frac{p_{02}}{p_{01}}, k_0, \frac{l_0}{d_0}, a_1 \sqrt{\frac{p_{01}}{H_1}}, \frac{p_{02}a_2 - p_{01}a_1}{\sqrt{p_{01}H_1}}, b_1, \frac{p_{02}b_2 - p_{01}b_1}{p_{01}}, \frac{p_{01}Q_1}{H_1}, \frac{Q_2}{Q_1} \right) \quad (3),$$

whence

$$\frac{L_x}{l_0} \simeq \Phi \left( \frac{p_{01}v_0^2}{H_1}, \frac{H_2}{H_1}, \frac{p_{02}}{p_{01}}, k_0, \frac{l_0}{d_0}, \frac{p_{01}a_2 - p_{02}a_1}{\sqrt{p_{01}H_1}}, \frac{p_{02}b_2 - p_{01}b_1}{p_{01}}, \frac{p_{01}Q_1}{H_1}, \frac{Q_2}{Q_1} \right). \quad (4)$$

is obtained on the assumption that  $a_1 \sqrt{p_{01}/H_1} \simeq \text{const}$  and  $b_1 \simeq \text{const}$ . The form of (4) is considered for five particular conditions of impact.

AUTHORS: Vitman, F. F.; Zlatin, N. A.

TITLE: Regular changes in flow limit at rapid loading rates and low temperatures

SOURCE: Fizika metallov i metallovedeniye, v. 15, no. 5, 1963, 796-798

TOPIC TAGS: flow limit, change, rapid loading, low temperature

ABSTRACT: This is a short answer to the criticism of the formula derived by the authors, expressing a relation between the flow limit ( $\delta_T^B$ ), deformation speed ( $\dot{\epsilon}$ ) and temperature (T):

$$\delta_T = D \left( \dot{\epsilon}^T \right)^n, \quad (1)$$

where D, B and n are the material constants. The authors support validity of this formula by experimental results obtained with a brittle soft steel. They conclude that the formula satisfies the experimental data at temperatures below recrystallization, providing that the deformation process is of an isothermal nature and is

"Structural physical factors and basic scientific problems in the strengthening of glasses and sitalls"

(Physicotechnical Institute, Academy of Sciences USSR)

At the Division of Physical Chemistry and Technology of Inorganic Materials, Acad. Sci. USSR, a scientific council on the problem of sitalls has been established. The Council is a coordinating body for basic scientific research on sitalls, glass, fiber glass, stoneware, refractory and superrefractory materials, and coatings. The purpose of the Council is primarily to contribute to the improvement of the strength and impact resistance of existing materials. In 1963, the council held two sessions.

TITLE: The strength of sheet glass and the scale factor

SOURCE: Fizika tverdogo tela, v. 6, no. 4, 1964, 1089-1095

TOPIC TAGS: sheet glass, crushing strength, scale factor, glass hardening, tester  
UM 5

TOPIC TAGS: Strength was measured by a UM-5 apparatus on samples 40 x 40 x 2.2 mm, by a weight-applying device for smaller sizes, and by a pneumatic machine for larger sizes. The duration of loading (till breakage) was the same for all samples (10-30 sec). The authors have shown that the strength of sheet glass hardened by etching in solutions of fluoric acid and also the strength of untreated glass depend markedly on the dimensions of the working (uniformly loaded) surface of the sample. When this surface is increased by a factor of 100 000, the strength is decreased several times. The authors investigate the statistical nature of this effect and show that it may be less noticeable, or even entirely absent, if the glass surface has an accumulation of defects strongly affecting the general dimensions of the

Card 1/2

ACCESSION NR: AP4028435

statistical function of defect distribution on the glass surface. The breaking of glassware most frequently occurs because of very local overstresses (blows). The local character of applying load is equivalent to a sharp limitation of any equally loaded operating surface on the glass. Hardened glass, in contrast to glass with numerous surface defects, reacts to blows as if the possible appearance of the scale factor were restricted. Consequently, whatever the dimensions of a piece of sheet glass in glassware, it should manifest, when struck, greater strength than when the same stresses act on the entire surface. This is one of the advantages of hardened glass; here the scale factor has a positive value. Orig. art. has: 4 figures and 2 tables.

TITLE: Fracture of a rod during the impact of two short tensile stress impulses

SOURCE: Fizika metallov i metallovedeniye, vol. 17, no. 3, 1964, 435-439

TOPIC TAGS: tensile stress, rod fracture, tensiometric measurement, friable state

ABSTRACT: The authors made an attempt to fracture a metal rod by simultaneously loading both ends by means of an explosion. By means of tensiometric measurements were explained the wave amplitude changes after the first collision, reflection from the ends of the second collision during which the structure of the tensile impulses cause the fracture of the rod. The paper proves that the methods used for loading the sample and recording of parameters of the waves along the rod make it possible to measure the strength of materials which approach a brittle state. The method used and the equipment are explained in detail. A tensiogram of the stress in a rod of U10A tempered steel is given. The amplitude measurements of the colliding waves are given in a table. In conclusion the authors claim that the examined method may be useful only in limited cases when the metal is very close to a brittle state. This method is therefore inapplicable to a wide range of plastic materials. Never-

Card 1/2

ACCESSION NR: AP4029003

theless, this method may be used for a comparative evaluation of the breaking resistance of tempered steels and to study the influence of a transition from a static to a rapidly occurring impulse load of the metal on this characteristic. The development of methods for measurement of break resistance in plastic materials with impulse loading should be continued for the purpose of limiting the influence of plastic deformation waves which accompany the propagation and decrease the amplitude of the running wave. Orig. art. has: 3 figures and 1 table.

TITLE: On the impact of deformable bodies and its simulation. 3. On the correspondence of the instantaneous values of the parameters of the simulated and simulating processes

SOURCE: Zhurnal tekhnicheskoy fiziki; v.34, no.3, 1964, 519-522

TOPIC TAGS: impact, deformable body, deformable body impact, simulation, impact simulation, deformable body impact simulation, steel dural impact, copper aluminum impact

ABSTRACT: On the basis of dimensional analysis, two of the authors have previously proposed the following general expression for the depth,  $L_K$ , of the crater formed by the normal impact of a body of revolution moving parallel to its axis on the plane surface of a large target (F.F.Vitman and N.A.Zlatin, DAN SSSR, 146, No.2, 337, 1962; ZhTF, 33, No.8, 982, 1963) and experimental evidence of its adequacy has been obtained (L.V.Belyakov, F.F.Vitman and N.A.Zlatin, Ibid. 33, No.8, 990, 1963).

Card 1/3

ACC.NR: AP4020582

$$\frac{L_n}{l_0} \approx \varphi_1 \left( \frac{\rho_0 v_0^2}{H_1}, \frac{H_2}{H_1}, \frac{\rho_{02}}{\rho_{01}}, k_0, \frac{l_0}{d_0}, \frac{\rho_{02} a_2}{\rho_{01} a_1} \right)$$

Here  $H$  is the "dynamic hardness" of the material,  $\rho$  is the density, and  $a$  is the velocity of sound.  $l$  and  $d$  are characteristic longitudinal and transverse dimensions of the projectile and  $k$  is a form factor describing the shape of the projectile head.  $v_0$  designates the impact velocity. The subscripts 1 and 2 refer to the target and projectile materials respectively, and the subscript 0 indicates the values prior to impact. It was hypothesized that not only the final crater depth  $L_K$ , but also the values assumed during the course of the impact process by all the relevant parameters are functions of the dimensionless quantities appearing in this equation and of an appropriate reduced time. To test this hypothesis, impacts of soft steel cylinders with dural targets and copper cylinders with aluminum targets were observed by an x-ray technique similar to that employed by V.A.Tsukerman and M.A.Manova (ZhTF, 24, No.2, 391, 1957). The materials and the impact velocities were so chosen that the dimensionless parameters in the above equation had the same values in the two cases. It was found that the penetration depth, the projectile length, and the maximum projectile width all were the same functions of the reduced time  $t/T$  for the steel-dural collisions as for the copper-aluminum collisions. Here  $t$  is the

Card<sup>2/3</sup>

ACC.NR: AP4020582

Time since contact and T is the duration of the impact process. T was 68 microsec for the steel-dural impact and 100 microsec for the copper-aluminum impact. Twelve x-ray photographs of the impacts are reproduced. Orig.art.has: 4 formulas and 3 figures.

TITLE: Increase of quenching stresses in glass for additional strengthening

SOURCE: AN SSSR. Doklady\*, v. 157, no. 1, 1964, 87-90

TOPIC TAGS: glass processing, glass annealing, heat treatment, strengthening, prestraining

ABSTRACT: A direct measurement was made of residual stresses in glasses with a wide range of thickness, quenched at different cooling rates, in order to compare the resultant data with the theory in the range of Biot numbers hitherto uninvestigated ( $Bi > 5$ ). This research was set up as a check on the hitherto prevalent opinion that quenching stresses cannot contribute much to further strengthening of glass. Glass plates 160 mm square and 5--25 mm thick were

Card 1/5

ACCESSION NR: AP4042020

quenched in two liquids having different cooling abilities. The fact that 25 mm plates quenched in liquid could lead to heretofore unattainable compression stresses on the order of 50 kg/mm<sup>2</sup> (double what can be accomplished with intense air quenching) indicates that the possibility of increasing quenching stresses have not yet been exhausted. The seeming discrepancy between the intense growth of compression stress and simultaneous strong attenuation of the tensile stresses is explained. Comparison of the experimental data with several theories of glass quenching shows that the theoretical calculations of V. L. Indenbom (Collection: Fizika tverdogo tela, 1, Izd. AN SSSR, 1959, page 236) are in better agreement with the test results than those of G. M. Bartenev (Mekhanicheskiye svoystva i teplovaya obrabotka stekla, 1960). The final conclusion is that one of the promising ways of strengthening thick glass still lies in the possibility of increasing the Biot number during their quenching and in the appropriate development of suitable quenching media. 5-, 8- and 12-mm thick specimens of glass (72% SiO<sub>2</sub>, 8% CaO, 15% Na<sub>2</sub>O, 3% MgO, 1.5% A<sub>l</sub><sub>2</sub>O<sub>3</sub>, 0.5% SO<sub>3</sub>) were divided into three groups: one group was subjected to tempering from 720°C in ethylpolysiloxane liquid heated to 120-140°C; another group, to etching in intensively stirred 20% HF; and the third group, to both tempering and etching. It was found that combined tempering and etching indeed produces the best results, enhancing the strength of thin-glass specimens to 100 kg/mm<sup>2</sup> and higher. These findings, incidentally, show that the old theories of the nature of the toughening of glass during tempering must be revised. The toughening effect in this case is not merely a result of an artificial relaxation of the tensile stresses in the glass; it is also associated with the rise of favorable physical changes in the rapidly cooled surface layers of glass. SOURCE: Fizika tverdogo tela, v. 8, no. 5, 1966, 1504-1510

TOPIC TAGS: quartz glass, glass property, temperature effect, glass product

ABSTRACT: It has been shown elsewhere that the strength of bulk sheet glass after etching in hydrofluoric acid solutions may be unusually high if the working surface of the glass is thoroughly protected from accumulations of defects before and during the experiment. The present investigation attempts to extend this finding to commercial bulk quartz glass and to study the influence of the temperature and the heat treatment on the strength of the quartz in its high-strength state (about 300 kg/mm<sup>2</sup>). It is found that if the action of the irreversible heat processes which softens the glass and the influence of moisture in various manifestations are excluded, the strength of the quartz glass in the 50-400C temperature range is independent of

TITLE: Safety factors and variation in the strength of plate glass

SOURCE: Fizika tverdogo tela, v. 7, no. 9, 1965, 2717-2722

TOPIC TAGS: sheet glass, high strength glass

ABSTRACT: It is shown that the values given in the literature for the strength of plate glass etched in hydrofluoric acid solutions are underestimated because insufficient attention is paid to possible accidental damage to the glass surface which may take place both before testing and while the glass is in the test installation. To verify this fact, special precautions are taken in testing the strength of glass after etching to see that damage to the surface is scrupulously avoided. A comparison with control experiments shows that the level of strength and dispersion in values observed in earlier experiments were due more to side factors than to the properties of the etched glass. The experimental data show that the guaranteed minimum values for the strength of the etched glass may be more than  $100 \text{ kg} \cdot \text{mm}^{-2}$ . When precautions are taken to avoid handling of the glass in any way after etching, ordinary window

2  
glass shows an average bending strength of  $\sim 250 \text{ kg} \cdot \text{mm}^{-2}$  with a much narrower spread in experimental values than previously observed. Measurements made in a dry vacuum to eliminate the effect of ambient humidity showed a more than double increase in strength. The experimental observations show that high strength is a property inherent in amorphous solids. It is suggested that the problem of producing high-strength glass may be solved not so much by developing methods for strengthening glass as by seeking ways to protect it from being weakened, since it is already in a super-strong state in its natural form. SOURCE: Steklo i keramika, no. 9, 1965, 12-14

TOPIC TAGS: sheet glass, glass property, hydrofluoric acid

ABSTRACT: Measurements of the strength of various parts of window glass before and after etching with hydrofluoric acid showed a great scatter of values (10–160 kg/mm<sup>2</sup> for etched glass). Measurements made after steps were taken to protect the etched surface from new flaws show that glasses reinforced by etching, i.e., freed from inherent and acquired surface defects, manifest their actual high-strength state if no accumulation of random damage is allowed to occur prior to and during the test. The observations lead to the important conclusion that the structural state of massive glass is in no way stronger than the state of glass fibers or drawn rods. Orig. art. has: 1 figure.

TOPIC TAGS: glass, glass product

ABSTRACT: This Author Certificate presents a method for strengthening glass and glass products by quenching them from the temperatures near the temperature of softening with the help of cooling substances. To prevent strength-lowering structural and physical alterations in glass during its hardening, glass is quenched with substances of the greatest cooling capacity exactly in the anomalous range of glass hardening temperatures.

TITLE: The high-strength state of glass

SOURCE: AN SSSR. Doklady, v. 163, no. 3, 1965, 617-620

TOPIC TAGS: glass property, high strength glass, hardening

ABSTRACT: The authors examine the reasons for the spread in individual strength values for glass hardened by various thermal and chemical methods. It is assumed that the high strength observed in certain specimens from a single batch of glass is not an accident, and that this high strength would show up in the majority of the glass specimens if it were not for strong suppressing side factors. These suppressing effects are attributed chiefly to atmospheric humidity and to possible damage of the glass during installation in the testing equipment. To test this hypothesis, experiments are conducted in which the glass is protected from harmful factors from the moment hardening is started. Strength measurements show that these precautions raised the minimum strength level noticeably in the scatter zone. However, it was found that weakening influences were not completely eliminated.

Card 1/2

L 1656-66

ACCESSION NR: AP5019427

2

Samples were then selected which were free from visible surface defects. This pre-caution further narrowed the scatter region and consequently increased the average strength of the batch of glass samples tested. Similar tests conducted with various types of glass hardened by various methods show analogous results. These experiments indicate that super-high-strength glass can be produced by finding practical ways to eliminate the weakening factors. It is recommended that further research should be done to determine just what these harmful factors are. Orig. art. has: 2 figures.

Voprosy aerodinamiki i teploperedachi v kotel'no-topochnykh protses-  
sakh; sbornik statey (Aerodynamic and Heat Transfer Problems in  
Boiler and Furnace Processes; A Collection of Articles) Moscow,  
Gosenergoizdat, 1958. 329 p. 6,000 copies printed.

Ed. (title page): Knorre, G.F.; Ed. (inside book): Borishanskiy,  
V.M.; Tech. Ed.: Zabrodina, A.A.

PURPOSE: The book is intended for engineers and combustion specialists concerned with the design and operation of heating equipment and it is also for scientific workers and students of vtuzes.

COVERAGE: The book presents the results of complex investigations of flow conditions and heat transfer in boiler and furnace processes. The compilation consists of three parts which discuss the conditions of atomization and combustion of liquid fuel, some problems of heat transfer and flow in furnaces and boilers and, finally, the results of investigations of the flow and heat transfer in a

Card 1/7

Aerodynamic and Heat Transfer (Cont.) 1053

layer of crushed material. The articles in the first part present the fundamental principles for calculating the atomization process in injectors. Also, new data on the combustion of droplets of heavy liquid fuel are given which make it necessary to reconsider the accepted concept that vaporization of a liquid fuel always precedes its combustion. The reports of the second part throw light on the problem of the motion of a dusty air stream characteristic of cyclonic furnaces. This problem is extremely important in the design of such furnaces. The second part of the collection presents data necessary for the calculation of the emission of fly ash whereby it is shown that this emission is of great significance. In addition, the character of furnace temperature fields is analyzed. The articles of the third part present the fundamental laws of gas flow through a layer of fuel and give the theoretical principles necessary for calculating the aerodynamic resistance of the layer and the speed of drying in it. The data given in the collection accurately define current ideas regarding the characteristics of development of a number of phenomena which form the

Card 2/7

Aerodynamic and Heat Transfer (Cont.) 1053

heating process. Knowledge of these data will permit refining the calculation methods used in heating technology. The first part contains 2 Soviet references; the second part contains 8 Soviet, 3 English, and 1 German reference; and the third part contains 49 Soviet, 12 English, 7 German, 1 French, and 2 Japanese references.

TITLE: Spraying Liquid Fuel With Pneumatic Nozzles

PERIODICAL: V sb.: Vopr. aerodinamiki i teploperedachi v kotel'notopokh. protsessakh. Moscow-Leningrad, Gosenergoizdat, 1958, pp. 5-3.

TEXT: A criterion dependence for determining the average diameter of drops of a sprayed jet was obtained, based on application of the theory of similitude to the problems of spraying viscous liquid in pneumatic sprayers. To study the effect of viscosity on the degree of fuel dispersion special experiments were carried out on a laboratory apparatus on which the following liquids were investigated: 5 different solutions of glycerin, with water, kerosene and benzine, for which the viscosity was changed from 1 to 60 Engler degrees and the surface tension coefficient from  $2.4 \cdot 10^{-3}$  to  $7.2 \cdot 10^{-3}$  kg/m. Formulas for dependences obtained in the above experiments were derived. With these formulas it was not possible to establish the changes of the drop diameter along the jet.

TITLE: Tidal tilts indicated by observations with photoelectric tiltmeters at Przhibrum (near Prague)

CITED SOURCE: Sb. Izuch. zemn. prilivov. No. 3. M., AM SSSR, 1963, 59-69

TOPIC TAGS: gravity field, tiltmeter, photoelectric tiltmeter, earth tide, tidal tilt, earth tide component

TRANSLATION: Photoelectric tiltmeters of the Institute of Physics of the Earth of the Academy of Sciences USSR were set up at Przhibrum in 1960 at a depth of 1,300 m near the horizontal pendulums of the Czechoslovakian Academy of Sciences. The electrodynamic constants of the tiltmeters were determined to an accuracy of 0.1-0.3%. The record of the tidal tilts was continuous with small gaps from June to December 1960. The behavior of individual components differed sharply from one another. Over a 7-month period the tilt in the north-south direction was 3" and in

Card 1/2

ACCESSION NR: AR4033593

the east-west direction 30°. This tilt was caused by the movement of two blocks along whose contact a mine working had been excavated. The rate of the tilting did not remain constant with time, which appreciably worsened the results of analysis of the tidal observations. Harmonic analysis gave the following mean values  $\gamma$  determined from the  $M_2$  wave:

$$\gamma_{N-S} = 0.665 \pm 0.011$$

$$\gamma_{E-W} = 0.702 \pm 0.019.$$

These figures indicate the existence of a real difference between  $\gamma_{N-S}$  and  $\gamma_{E-W}$  at Prshibra. B. Pertsov

Reduction of carbon dioxide in a carbon channel. L. A. Vulli and L. Ar-Vitam... *J. Tech. Phys.* (U. S. S. R.) 11, 500-18(1941).—Preheated CO<sub>2</sub> flowed through a cylinder of electrode carbon of uniform temp. (900° to 1150°), varying in length (34, 52, 57, 85 and 98 mm.) and inner diam. (4-6 mm.); standard condition of the canal surface was attained by preliminary heating in a N atm. for 1.5 to 2 hrs. By varying the thickness of the canal wall, it was proved that the reaction rate depends solely on the inner dimensions of the canal surface. The reaction, measured by analysis of the gas leaving the canal, is shown, at 900° and, practically, also at 1050°, to be independent of Reynolds' no.; in this temp. interval (the "kinetic" region), plotting of the compn. of the gas leaving the canal against the gas output shows the reaction C + CO<sub>2</sub> = 2CO to be of the first order, with an activation energy *B* = 56 kg.-cal./mole and *k* = 3.10<sup>6</sup> cm./sec. In the "intermediate" region, where kinetic and diffusion processes become commensurable, a graphic method permits an approx. sepa. of the two phenomena. Comparison with

the reaction between C and O<sub>2</sub> leads to the conclusion that the C + CO<sub>2</sub> reaction has a negligible velocity below 900°. At temps. still higher than those used in this investigation, 1300 to 1500°, calc'd. shows that the reaction comes near the pure diffusion region, its rate becoming commensurable with that of the reaction C + O<sub>2</sub>. The exptl. results demonstrate further the utter inapplicability of the formula of Clement, Adams and Hawks (C. A. 6, 800); it has been found, at 1000°, with *R* (Reynolds' no.) 100, *r* (time of contact) 3.8 × 10<sup>-3</sup> sec., 16% CO was formed; 1000°, *R* 1000, *r* 3.8 × 10<sup>-3</sup> sec., 5% CO; at 1100°, *R* 100, *r* 3.1 × 10<sup>-3</sup> sec., 40% CO; 1100°, *R* 1000, *r* 3.1 × 10<sup>-3</sup> sec., 12% CO. These exptl. findings are 100 to 500 times higher than the data calc'd. by the formula. N. Thru
