Title: Effects of Separation on Qualitative Composition of Beer Wort

Original  
Periodical:

Tr. Kievsk. tekhnol. in-ta pishchevoy prom-sti, 1953, No 13, 101-105

Abstract: Studies of qualitative changes in turbid beer wort on 5-minute centrifugation in laboratory precipitation centrifuge at 2,000 RPM. The indexes thus obtained are compared with those of clear wort (CW) collected from outlet of filter-press after filtration of turbid liquor that was concurrently subjected to separation. Residue of insolubles in CW was the same within 0.01-0.03 g/100 ml. Turbidity of separated CW is almost 2 times less due to more complete removal of colloids both prior to and after hop treatment of the wort. Color and pH of CW are the same. Protein content and dextrin content of CW are practically the same.

5022. LESIONS OF THE HYPOTHALAMIC REGION DUE TO INFLUENZA  
(Russian text) - Vyalov A.M. - ZH. NEVROPAT. I PSIKHIAT. 1959, 59/3  
(261-264)

In the clinical picture of hypothalamic lesions, 2 groups of symptoms are distinguished, according to the functions of the hypothalamus. The following 2 groups of symptoms characterize the diencephalic syndrome: (a) Asthenia; adynamia; sudden occurrence of dyspnoea; either retardation or acceleration of respiration; change in the ratio between length of inspiration and that of expiration; vasomotor lability; disturbed oculo-cardiac, pharyngeal and epigastric reflexes, and, finally, a change in blood pressure. (b) On the other hand, the following symptoms are also reported: anorexia and bulimia; oligodipsia and polydipsia; subfebrile and subnormal body temperatures; asymmetry of skin temperature; disturbed non-conditioned thermo-regulatory reflex (Tcherbak); and sleep disturbances. In particular, it is to be remarked that subfebrile temperature, if not accompanied by other signs of hypothalamic disturbance, cannot be attributed to damage to the tegmentum in the region of the 3rd ventricle. Generally, this indicates disturbances in other parts of the thermoregulatory system. (L, 8)

Purification of zinc sulfate solutions by extracting iron.  
B. V. Oronov and A. V. Vyslov, *Tsvetnoye Metal.* 1939,  
No. 7, 92-7.—Fe is extracted from neutral  $ZnSO_4$  solns.,  
which are first neutralized by adding Zn drops or a reagent  
contg.  $ZnO$  or  $ZnO_2$ ;  $MnO_2$  is then added to oxidize the Fe  
to Fe and ppt. it. Nearly all of the Fe is pptd. Accurate  
pH control is necessary for the success of the new method.  
The probable reaction is:  $2FeSO_4 + MnO_2 + 2H_2O =$   
 $2FeO(OH)_2 \cdot H_2O + MnSO_4$ . The probability of this  
reaction is supported by the  $H_2O-FeO_2-SO_4$  diagram of  
Pomniak and Mierwin (*C. A.* 16, 3799), where insol. Fe  
salts are shown, which agree closely with the salt in the  
above reaction. The pH of the soln. should be maintained  
between 3.5-4.5. In practice, a side reaction,  $2FeSO_4 +$   
 $MnO_2 + 2H_2O = Fe_2O_3 \cdot H_2O + MnSO_4 + H_2SO_4$ , takes  
place in weakly acid solns., tending to lower the pH of the  
soln., with accompanying formation of stable colloidal  
solns. of Fe and solns. of Fe salts; this makes filtration dif-  
ficult. To counteract this effect, the use of small amounts of  
Zn drops (0.8 kg. per cu. m. of soln.) quickly precipitates  
the  $Fe(OH)_3$  soln. without appreciable change in the pH  
of the soln. B. N. Daniloff

TITLE: Some problems arising in the formation of a magnetic field by a current

PERIODICAL: Zhurnal tekhnicheskoy fiziki, v. 32, no. 11, 1962, 1361-1370

TEXT: The build-up of a given magnetic field by a plane current in a multi-layer magnet is investigated. Three cases are considered:  
(1) no interface (homogeneous magnet), (2) magnet with one interface and  
(3) with two interfaces. The current is calculated from the magnetic field produced by itself. The problem leads to the solution of a two-dimensional Fredholm integral equation of the first kind. The arbitrariness in the definition of the intensity of magnetization  $\vec{M}$  is avoided by considering only a plane current:

$$\rho(r) = \rho_x i + \rho_y j + \rho_z k \equiv \rho_x i + \rho_y j, \quad (1.7)$$

$$\rho_z = 0, \quad (1.8),$$

$$\mathbf{M}(r) = M_x(r) \cdot \mathbf{i} + M_y(r) \cdot \mathbf{j} + M_z(r) \cdot \mathbf{k} = M_x(r) \cdot \mathbf{i} + M_y(r) \cdot \mathbf{j}, \quad (1.9)$$

Card 1/4

Some problems arising in the ...

S/057/62/032/011/007/014  
B104/B102

where it is required that  $M(x, y, z)$  at infinity should vanish with the current. The solution of the system

$$\text{rot } \mathbf{H}(\mathbf{r}) = 4\pi\rho, \quad (1.1)$$

$$\text{div } \mathbf{H}(\mathbf{r}) = \frac{1}{\epsilon(\mathbf{r})} \mathbf{H}(\mathbf{r}) \cdot \text{grad } \epsilon(\mathbf{r}), \quad (1.4)$$

$$\epsilon(\mathbf{r}) = \frac{1}{\mu(\mathbf{r})}. \quad (1.5)$$

is sought in the form  $\vec{H}(\vec{r}) = 4\pi\vec{M}(\vec{r}) + \vec{h}(\vec{r})$ , where  $\vec{h}$  is determined from

$$\text{rot } \mathbf{h}(\mathbf{r}) = 0, \quad (1.11)$$

$$\text{div } \mathbf{h}(\mathbf{r}) = 4\pi M \frac{1}{\epsilon} \text{grad } \epsilon(\mathbf{r}) + \frac{1}{\epsilon} \mathbf{h} \cdot \text{grad } \epsilon(\mathbf{r}) - 4\pi \text{div } \mathbf{M}(\mathbf{r}). \quad (1.12).$$

Lengthy calculation leads to

$$M(p, q, a, b) = \frac{h(p, q)}{2\pi \left[ \sigma\left(\frac{p, q, 0}{a}\right) - \sigma\left(\frac{p, q, 0}{b}\right) \right]}, \quad (1.26)$$

Card 2/4

Some problems arising in the ...

S/057/62/032/011/007/014  
B104/B102

$$\sigma\left(\frac{p, q, z}{\zeta}\right) = \sigma_0\left(\frac{p, q, z}{\zeta}\right) - \sum_s a_s \sigma_0\left(\frac{p, q, z}{z_s}\right) \sigma^{(s)}. \quad (1.27)$$

where the  $n$  quantities  $\sigma^{(s)}$  are determined from the system of  $n$  linear algebraic equations.

$$\sigma^{(s)} + \sum_p a_p \sigma_{(sp)} \sigma^{(p)} = \sigma_0^{(s)}. \quad (1.28).$$

This expression is discussed for the three special cases mentioned above, and it is shown that the value  $M_0(x, y, a, \Delta)$  of the density of magnetization required for the production of a given field in a homogeneous magnet is important.  $a$  is the distance to the midplane  $z = 0$ . If  $M_0(x, y, a, \Delta)$  is known as an analytic function it becomes possible to arrive at the exact expression for the equivalent

Card 3/4

Some problems arising in the ...

S/057/62/032/011/007/014  
B104/B102

magnetization when account is taken of the effect of the interfaces for infinitely thin current layers ( $\Delta \rightarrow 0$ ) situated very near the interface. The corrections for finite thickness  $\Delta$  of the current layers and for the finite distance  $d$  of the current from the interfaces can be obtained by successive approximations.

p 495 (USSR)

## ABSTRACT:

An apparatus was developed which renders it possible to shift automatically ground sections under the microscope so that 1200 fields, i.e. a sample surface of 15 x 65 mm may be viewed successively. The apparatus (Fig) is mounted with the stage of the microscope and consists basically of a small device operated by an electric motor. The shifting of the ground section is done by means of two pairs of worm threads transmitting the rotation of the electric motor via a cog wheel. As soon as the section has shifted by 15 mm a lengthwise shift by 0.8 mm follows, etc. The apparatus described has already been used for five years in the metallographic laboratory of the Kuznetsk Metallurgical Kombinat. There is 1 figure.

TITLE: The Paleogene of the Southern Shore of the Kara-Bogaz-Gol (Paleogen yuzhnogo poberezh'ya Kara-Bogaz-Gola)

PERIODICAL: Tr. In-ta geol. AN TurkmenSSR, 1956, Vol 1, pp 163-171

ABSTRACT: A brief description of the Paleogene razrez (section) in the region of the southern shore of the Kara-Bogaz-Gol is given on the basis of work done in 1938. 1) A variegated marl formation, 34 m thick, rests on Danian limestones. White marls predominate in the lower part, red spotted marls in the middle part, and variegated marls with layers of calcareous clays in the upper part. Fossils have not been found in the formation. 2) Next occurs a white marl formation, 23 m

Card 1/2

15-57-12-16794

## The Paleogene of the Southern Shore (Cont.)

thick, which is divided into three members on color and lithology.  
3) A brown (fish) horizon, 23 m thick, consists of shaly marly clay and thinly platy argillaceous marl, with thin layers of "gilyaba" (a bleaching clay) in the lower part (the lower boundary of the horizon is placed at the first appearance of a layer of gilyaba). Large quantities of small fish scales are present in the sequence.  
4) A formation of green calcareous clay, 20 m thick, produces platy rubble; the calcareous content decreases upward. 5) A formation of green clays and sands, approximately 50 m thick, occurs next in the section. The number and thickness of sand layers reach their greatest values in the middle part of the unit. 6) A formation of green platy clays, approximately 100 m thick, contains small fish scales and, in the upper part, indeterminate pelecypod imprints. In addition, the author compares the Kizyl-Kup razrez (section) with other regions and gives a table showing the comparison of the sections.

SUBJECT USSR / PHYSICS  
AUTHOR VJALOV, G.N.  
TITLE The Anomalous Magnetic Moment of Nucleons.  
PERIODICAL Zurn.eksp.i teor.fis,31,fasc.4,620-624 (1956)  
Issued: 1 / 1957

CARD 1 / 2

PA - 1781

In the present work the anomalous magnetic moment of nucleons is computed in consideration of their excited states and on the basis of the semi-phenomenological theory of the interaction between pions and nucleons (I.E.TAMM et al, Zurn.eksp.i teor.fis,26,649, 1954). All quantities are given with FEYNMAN'S denotations.

At first the rather voluminous LAGRANGIAN of the system of nucleons and mesons in the electromagnetic system for the symmetric pseudoscalar meson theory with mixed pseudoscalar and pseudovectorial coupling of the meson field with the nucleon field is given. By variation of the LAGRANGIAN with respect to  $\Psi$  and  $\vec{B}$  in the case of the validity of the additional condition  $B_{\mu} \bar{\psi}_{\mu} = 0$ , equations for the wave functions  $\Psi$  and  $B_{\mu}$  are obtained. These equations are transformed and solved by FEYNMAN'S method with the help of the inverse operator

$(L^{-1})_{\alpha\beta} = K_{\alpha\beta}$ . - There follows the computation of the matrix elements: Here the contribution made by the diagrams represented by a drawing to the anomalous magnetic moment of the nucleons is computed. Because of the great singularity of the inverse operator  $K_{\mu\nu}$  the matrix elements diverge considerably (divergence of the fourth order). This divergence is eliminated by the introduc-

Zurn.eksp.1 teor.fis.,31,fasc.4,620-624 (1956) CARD 2 / 2 PA - 1781  
tion of FEYNMAN'S cut-off factors. In order to simplify computations, cutting-  
off is not carried out within the entire matrix element at one and the same  
time but separately in each summand.

Numerical results; discussion: The numerical result for the anomalous magnetic  
moment  $\delta\mu$  depends on the sign of the constant  $g$  of the pseudovectorial cou-  
pling. When using the values  $g^2=0,2$ ;  $g_1^2=0,13$ ;  $s=2$ ;  $M_1=m+2,25\mu$ ;  $\epsilon=1,61$   
one finds for  $g > 0$  and  $\lambda \sim m$  for the anomalous magnetic moment of the pro-  
ton and neutron  $\delta\mu_p \sim 1,5\mu_0$ ;  $\delta\mu_N \sim -1,3\mu_0$  respectively. With an increasing  
 $\lambda$  the absolute values of  $\delta\mu_p$  and  $\delta\mu_N$  increase, on which occasion their re-  
lation remains approximately unchanged. Thus it is possible, by a suitable se-  
lection of the cut-off parameter  $\lambda$ , to attain quite good agreement between  
theory and experiment. Approximately the same conclusions were arrived at by  
A.KANAZAWA and M.SUGAWARA, Prog.Theor.Phys.,11, 231 (1954), but the author  
describes his own computations as being more consistent and more accurate.  
Thus, the additional interaction between nucleons and the electromagnetic  
field (constant  $\epsilon$ ) was not taken into account by the above cited work. The  
contribution made by this additional interaction towards the anomalous magnetic  
moment is of the same order as other types of interaction and must therefore be  
taken into account.

TITLE: Computation of phase relationships in a cyclotron

SOURCE: Atomnaya energiya, v. 16, no. 5, 1964, 442-444

TOPIC TAGS: cyclotron phase shift, magnetic field drop, cyclotron ion energy, phase shift computation, cyclotron

ABSTRACT: The equation for the phase shift in the cyclotron contains (in addition to the universal constants) the final ion energy, the phase, and the amplitude of the accelerating potential. The parameters of the cyclotron can easily be computed if the magnetic field changes parabolically along the radius, or linearly as a function of the relative ion energy (in comparison with the final energy). The author found it convenient, in his analysis of numerous cases of magnetic drop, to approximate the latter with linear segments. Measurements show that the magnetic field of the cyclotron of the Laboratory for Nuclear Reactions of the Consolidated Institute for Nuclear Investigations can be closely approximated by three straight lines. Orig. art. has: 1 figure, 22 equations.

SOURCE: Yadernaya fizika, v. 2, no. 1, 1965, 112-116

TOPIC TAGS: electrostatic field, electrostatic acceleration, ion beam, beam velocity

ABSTRACT: The possibility of high-current acceleration of heavy ions by changing the ion charge was investigated analytically. The nonpotential characteristic of the product ZE under the integral of the energy equation is shown by

$$\Delta W = W_2 - W_1 = e \int Z(E dr)$$

The optimum potential required to impart the maximum energy to the accelerating ion beam with given energy  $W$  is calculated and is given by

$$V_o = [Z_i(W) - Z_c(W)] / 2eZ_i(W)Z'_c(W)$$

The various mechanisms for causing intensity losses in the multiple acceleration

scheme described above are listed. For a constant  $\Delta W$  the mean multiple scattering angle at small angles is given by  $\langle \theta_m^2 \rangle = \text{const} / \Delta W \cdot W_0$ .

The scattering cross section for the large angle aperture accelerator is given by

$$\sigma(\theta_L) = \frac{n e^4 Z_0^2 Z_1^2 \cos \theta_L}{W^2} \left[ 1 - \frac{A_0^4}{A_1^2 \sin^2 \theta_L} \right]^{1/2}$$

and the beam intensity by

$$I_0 = \left[ \sqrt{\frac{\pi}{2}} \int_0^{\infty} \exp\left(-\frac{t^2}{2}\right) dt \right]^2 \rightarrow P(\theta_L)$$

It is shown that for all elements high intensity ion beams can be obtained with the limiting energy  $W_n = 0.125 A_0 Z_0^4 \text{ MeV}$ . "The authors express their gratitude to corresponding member of the AN SSSR, G. N. Flerov, for his continuous interest in the work and to Professor M. I. Podgoretskiy for his valuable advice and evaluation of the problem." Orig. art. has: 13 formulas. [04]

AUTHOR: Vyalov, G. N.

TITLE: Method of calculating the shape of a magnet from a given field

PERIODICAL: Zhurnal tekhnicheskoy fiziki, v. 32, no. 3, 1962, 287 - 293

TEXT: The author determines the shape of one-dimensionally magnetized iron shims which produce a given z-component of the magnetic field in the central plane of a magnet. With known magnetization  $\vec{M}(\vec{r})$  (e. g., with homogeneous magnetization of the iron along the z-axis) the lower boundary of the iron shims applied to the plane  $z = z_0$  and changing the field strength in the central plane by  $\delta \vec{H}(x, y)$  is sought. Owing to the disturbing effect of the pole boundaries the author first determines the shape of the magnetic shims from the field produced by them, and then takes account of the effect of the poles. From the scalar potential

$$(1,4) \quad \Phi(\vec{r}) = \iint_{-\infty}^{\infty} dx' dy' M(x', y') \left[ \frac{1}{|\vec{r} - \vec{r}_0|} - \frac{1}{|\vec{r} - \vec{r}_1|} \right],$$

Card 1/4

Method of calculating ...

S/057/62/032/003/004/019  
B125/B102

the following integral equation is obtained for the z-component of the magnetic field  $\vec{H} = -\text{grad}\phi$  in the central plane  $z = 0$ :

$$\delta H(x, y) = \iint_{-\infty}^{\infty} dx' dy' M(x', y') \left[ \frac{\partial}{\partial x} \left( \frac{1}{|r - r'_1|} - \frac{1}{|r - r'_0|} \right) \right]_{r=0}. \quad (1,5)$$

$\vec{r}_0$  and  $\vec{r}_1$  denote points in the planes  $z = z_0$  and  $z = z_1$ , and  $M(x, y) = M_z(x, y)$ . The sought thickness  $\Delta(x, y, z_0) = z_0 - z_1(x, y)$  is much smaller than the distance  $z_0$  from the central plane. For this reason, the expression under the integral sign of (1,5) is expanded into a power series of  $\Delta(x', y', z_0)/\sqrt{(x-x')^2 + (y-y')^2 + z_0^2}$  (2,3), and (1,5) is transformed to

$$(2,4) \quad \epsilon \iint_{-\infty}^{\infty} dx' dy' K(x - x', y - y', z_0) f(x', y', z_0, \epsilon) M(x', y') = \\ = \epsilon h(x, y) - Q(x, y, \epsilon),$$

Card 2/4

S/057/62/032/003/004/019  
B125/B102

Method of calculating ...

where  $\epsilon$  is a small parameter:  $\mathfrak{M}(x, y, z_0) = \epsilon f(x, y, z_0, \epsilon), \epsilon H(x, y)$   
 $= \epsilon h(x, y)(2,5)$ . From the linear integral equation for  $f_n(x, y, z_0)$ ,

$$\mathfrak{M}(x, y, z_0) = \frac{1}{(2\pi)^2} \int_0^\infty d\lambda e^{\lambda y} \int_{-\infty}^\infty dx' dy' J_0(\lambda p) h(x', y'). \quad (3,6)$$

is obtained

for the thickness of the magnetized layer, by the Fourier method. For the one-dimensional case

$$(3,7) \quad \mathfrak{M}(x, z_0) = \frac{1}{(2\pi)^2} \int_{-\infty}^\infty dp \frac{e^{iz_0|p| + ipx}}{|p|} \int_{-\infty}^\infty dx' h(x') e^{-ipx'}.$$

is obtained, in polar coordinates

$$(3,8), \quad \mathfrak{M}(r, \varphi, z_0) = \frac{1}{(2\pi)^2} \int_0^\infty d\lambda e^{\lambda r} \int_0^\infty r' dr' \int_0^{2\pi} d\varphi J_0(\lambda r) h(r', \varphi).$$

and in the axisymmetrical case

$$(3,9). \quad \mathfrak{M}(r, z_0) = \frac{1}{2\pi} \int_0^\infty d\lambda e^{\lambda r} J_0(\lambda r) \int_0^\infty r' dr' J_0(\lambda r') h(r').$$

Card 3/4

S/057/62/032/003/004/019  
B125/B102

Method of calculating ...

The function  $M(x, y, z_0)$ , which cannot be represented in compact form with  $z_0 > 0$  but with  $z_0 < 0$ , can be analytically continued into the region  $z > 0$ .  
Thus, the final result  $M(x, z_0) = \frac{1}{2\pi i(n-1)} \left\{ \frac{1}{[x+i(a-z_0)]^{n-1}} - \frac{1}{[x-i(a-z_0)]^{n-1}} \right\}$ . (4,9)

is obtained for the region  $0 < z < a$ . The effect of the poles on the field of the shims and the convergence in the successive approximation to the thickness of the sought layer must also be determined. V. V. Babikov and I. I. Royzen are thanked for discussions. There are 6 references: 2 Soviet and 4 non-Soviet.

TITLE: Pipe rolling mill. Class 7, No. 183693 [announced by the Elektrostal' Heavy  
Machine Building Plant (Elektrostal'skiy zavod tyazhelogo mashinostroyeniya)]

SOURCE: Izobret prom obraz tov zn, no. 14, 1966, 9

TOPIC TAGS: pipe, rolling mill

ABSTRACT: This Author's Certificate introduces: 1. A pipe rolling mill consisting of a housing with drive and input and output equipment. The housing is equipped with pilger mill roller and automatic mill roller assemblies. 2. A modification of this device for producing tubes by the pilger method. The unit has a feed mechanism, a mechanism for controlling mandrel cooling and transfer, and a lifting trough on the input side. The output side of the mill is equipped with a lift table. 3. A modification of this unit for automatic pipe rolling using master rollers on the input side of the mill to replace the hoisting trough. The unit also has a fixed trough, while a single assembly consisting of wiring, crosspiece and brake-centering unit is mounted on the output side of the mill.
