TEXT: Reactor control of induction motors on small winders
is considered. An uncontrolled starting reactor in the rotor
circuit, and parallel-series resistance, gives smooth automatic
acceleration to maximum speed with the minimum of starting
equipment. The disadvantages of this circuit are: the high
starting torque, which causes high dynamic loading of the machine
and rope; the relatively high starting current compared with
contactor control; and the impossibility of controlling the
speed. The control circuit with a saturating reactor in the rotor
circuit combined with an uncontrolled reactor ensures smoother
application of starting torque. Experimental investigations of
the influence of starting conditions on the magnitude of dynamic

loads in components of the winder, with contactor and with reactor control, showed that the maximum torque in the main shaft occurred at the instant of starting. With smooth application of starting torque the amplitude of tensile stress in the winding rope is about 40-50% of the weight of the useful load. Various arrangements and mechanical characteristics for dynamic braking of the winder motor with a saturating choke in the rotor circuit are considered. A two-induction motor drive circuit is proposed. There is an uncontrolled starting reactor in the rotor circuit of the first motor; in that of the second motor are an uncontrolled reactor and a saturating reactor which is necessary for smooth starting. During braking the second motor exerts controlled dynamic retardation and the first motor continues to operate under motor conditions. The overall mechanical characteristics of this system are given.

TITLE: Pneumatic Three-Jaw Chucks (Pnevmaticheskiye trekhkulachkovyye patrony)

PERIODICAL: Mashinostroyitel', 1958, Nr 10, pp 22 - 24 (USSR)

ABSTRACT: Simple, safe and reliable pneumo-automatic chucks, developed at the Leningradskiy ^{zavod} "Pnevmatika" (Leningrad "Pnevmatika" Plant), are of 4 types with respect to dimensions (table 1) and can be used for all turning operations in machine-building. The plant also produces special two-jaw chucks for pressed blanks of intricate profile. The pneumatic chucks reduce time-consuming operations in handling blanks during machining on turning and turret lathes. The front mandrel of a turret lathe of the zavod imeni Ordzhonikidze (Plant imeni Ordzhonikidze) is shown (photo 1), and the pneumatic chuck, air duct, press button panel, and the pneumatic system is explained (figs. 2 and 4). The chuck design also permits machining of parts from long blanks as is shown in the chuck attachment to the LD62 machine (fig. 5). There are 4 sets of diagrams, 1 photo and 1 table.

A micro test for potassium. V. V. Bulychev. *Zhur. Anal. Khim.*, 2, 242-3 (1947); cf. *Kaiga*, C. A. 41, 6177. The test for K with NaI₃ as outlined by Kaiga is interfered with by the presence of NH₄. NH₄ is removed by converting it to NH₃ and then fixing it with CH₃CO₂ a soln. to be tested for K; and evap. NH₃, add a drop of phenolphthalein and 1-2 drops of 1.0 N NaCl₃ soln. Add CH₃CO₂ dropperwise until the soln. becomes colorless. Wait 1-2 min. and add more CH₃CO₂ if necessary. Place a drop of the soln. on a microscope slide, add a drop of NaI₃ reagent and look for the characteristic KPI₃·CH₃CO₂ crystals. The reagent should be added sparingly according to the K content lest the crystals of KPI₃·CH₃CO₂ dissolve in the reagent. M. Hirsch

TITLE: Volumetric-gravimetric Determination of Titanium in Steel
(Ob'yemno-vesovoye opredeleniye titana v stali)

PERIODICAL: Uch. zap. Kazansk. un-ta, 1957, Vol 117, Nr 9, pp 204-206

ABSTRACT: The use of 0.01-M solution of methylene blue is proposed for the determination of small amounts of Ti in steel. The analysis is performed on 1.0-1.5-g specimens of steel. The specimens are dissolved in 2N H₂SO₄ and H₂S is passed through the solution in order to separate Cu and Mo. 2-5 drops of H₂O₂ are added to the filtrate, which is heated to 70-80°C and 50 cc of KOH solution are added. The precipitate is separated, dissolved in 10-15 cc of concentrated HCl, and the solution is diluted to the mark in a 50-cc flask after which aliquot portions (10 and 5 cc) are taken. Ti⁴⁺ is then reduced to Ti³⁺, and the solution is heated and titrated with the solution of methylene blue to discoloration. The verification is performed on a standard specimen of Nr-51 steel. The relative error of the Ti determination is ± 0.11% (relative). Z. G.

inability

ABSTRACT: Previous studies have shown that propellants containing
polystyrene and NH₄CIO₄ with small size particles (15 μm) burn slowly
and rapidly with large particles size (middle 100--400 μm). This
is due to the fact that interaction with the small particles
oxidizer, the reaction in the interaction zone takes place at an excess
of oxidizer. When part of the small size oxidizer is replaced by a
large size oxidizer, the mixture is enriched in fuel and the reaction
rate increases. The authors studied the burning rate of polystyrene
and polystyrene mixtures at different ratios.
The burning rate of the mixture is proportional to the ratio of
the smaller particle sizes of 1, 2, 5, 10, 20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 220, 240, 260, 280, 300, 320, 340, 360, 380, 400, 420, 440, 460, 480, 500, 520, 540, 560, 580, 600, 620, 640, 100% FUEL

In addition to the above experiments were made at 5, 10, 15, 20,
25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95
and 100% OXIDIZER. In mixture of large and small particles.
It was found that the propellants within the mixed particle
oxidizer can burn at any rate ranging from that of the large particle
size to that of the small particle size depending on the fuel/oxidizer

the fact that the burning velocity becomes less dependent on pressure

TITLE: Accuracy of the deposition of film coatings on the surface of textile materials

SOURCE: IVUZ. Tekhnologiya legkoy promyshlennosti, no. 1, 1966, 58-67

TOPIC TAGS: textile industry machinery, protective coating, chemical deposition, error statistics

ABSTRACT: Using bottoming machines with doctor systems as an example, the authors consider equipment and technological process errors affecting the accuracy of deposition of a coating. An attempt is made to treat these errors mathematically. Methods of eliminating these errors, adjusting the equipment and controlling the accuracy are discussed in terms of theoretical probability and statistical calculations. In order to increase the accuracy of the deposition of coatings, the bottoming machines should be equipped with automatic devices which eliminate the

dominant and mainly the variable factors; in addition, prime coats with tolerances specified by GOST and bottoms of stable quality should be employed. Recommendations are given for a maximum economy of chemical materials during the deposition of coatings. Orig. art. has: 4 figures.

TITLE: The effect of low temperature on the antifriction properties of polycaprolactam

SOURCE: Plasticheskiye massy*, no. 9, 1964, 41-43

TOPIC TAGS: polycaprolactam, polyamide, friction, abrasion, lubricant, low temperature lubrication, Kapron

ABSTRACT: Since the antifriction properties of polyamides at low temperature have not been investigated thoroughly so far, the abrasion and the coefficients of friction of Kapron on steel, with and without lubricants, were investigated at 20-25°C without preliminary cooling of the samples, at 20-25°C with preliminary cooling at -50°C for 10 and 20 days, and at -50°C, first under a constant specific pressure of 30 kgs/cm², at different rates of abrasion (0.25, 0.5, 0.99 and 1.95 m/sec.) and then at a constant abrasion speed of 0.5 m/sec. and different pressures: 10, 30, 50 and 75 kgs/cm². Cylindrical polycaprolactam and bronze samples were used. A steel disk was used as the abradant. The investigations were carried out on a lathe equipped with a device which permitted adjustment of the load and temperature required for the sample and the setting of the moment of friction. The tester is illustrated. The experiment took 60 min. at room temperature and 20 min.

Card 1/3

ACCESSION NR: AP4045024

at -50C. The length of the abrasion path varied from 500-7000 mm, depending on the time and rate of abrasion. The samples were washed carefully in alcohol, dried at +60C and weighed, the difference in weight being a measure of the degree of abrasion. It was found that the surface of the samples shows cracks after prolonged cooling. The dependence of the degree of abrasion and coefficient of friction on the rate of abrasion and pressure is plotted. It is concluded that the friction of Kapron on a steel disk with a lubricant at positive temperatures results in slight abrasion in all cases. The same was observed for the abrasion of bronze on steel. On abrading Kapron with steel without a lubricant at positive temperatures, the abrasion was slightly higher than that with a lubricant. The abrasion of bronze samples with a lubricant was high compared to the abrasion of Kapron without a lubricant or that of bronze with a lubricant. On abrading Kapron with steel with and without a lubricant at low temperature (- 50 C), the abrasion values and coefficients of friction differed only slightly from one another and approached the values obtained at positive temperatures. After maintaining Kapron samples at a low temperature (-50C) for 10 or 20 days, their antifriction properties decreased (the coefficient of friction and abrasion increased), but the antifriction properties of bronze remained almost unchanged. Orig. art. has: 5 figures.

TITLE: The gravimetric survey with marine static gravimeters on the
Okhotskoye Sea and Pacific Ocean

PERIODICAL: Referativnyy zhurnal, Astronomiya i Geodeziya, no. 2, 1962, 26,
abstract 20160 (v sb. "Prikl. geofizika", no. 29, Moscow, 1961,
136 - 156)

TEXT: The purpose of research was the study of depth structure of the
Earth's crust in the transition zone from the Asiatic continent to the Pacific
in the region of the Kurilo-Kamchatka island row. The observations were conducted
from a moving ship with quartz non-astatisized gravimeters with horizontal fila-
ment and liquid temperature compensation, provided with strong damping and mounted
on Cardan suspension. The measurements were carried out simultaneously with three
gravimeters, two of which were equipped with photorecording devices. The magni-
tude of a random error in measurements with the group of instruments did not ex-
ceed ± 1.8 mgal. The accuracy of visual observations was somewhat lower than the
accuracy of measurements with photorecording. In processing the results were ✓

introduced the corrections of Etvoes and Pray (for depth) and anomalies of Fay and Bouguer were then calculated. The density of the intermediate layer was assumed to be 2.65 and water density - 1.03. For all three profiles the curves of gravitational field in Fay reduction almost do not differ from each other. The Okhotskoye Sea is characterized by a weak positive field, a small coastal effect distinctly appears at the Sakhalin shelf. The coastal effect is greater in the zone of the Kuril'skaya arc. In the Ocean the curve of Fay anomalies remains in the region of positive values, which are larger than on the Okhotskoye Sea. The authors calculated for the southern and northern profiles density drops from the upper boundary to the lower one, and the densities proper for three layers in the northern section and four layers in the southern one.

TITLE:
Experience from work with the First Nuclear Power Plant

PERIODICAL: Atomnaya energiya, v. 11, no. 1, 1961, 12 - 18

TEXT: The First Nuclear Power Plant in the USSR, which was the first in the world, has been successfully operated for seven years; this paper presents a short survey of the experiences accumulated during the first six years at this station. The station itself possesses all the equipment available at a large research reactor. The construction of the Beloyarskaya GRES (Beloyarsk State Regional Electric Power Plant) represents a further development of the First Nuclear Power Plant. The working of the reactor at different power levels: In the so-called "cold state", at 0.01% of the nominal power, the reactor has the lowest power level at which the automatic power regulator can still function; the rise in this level is checked by measuring the neutron flux; the power level can be doubled within 20 sec.

Card 1/9

Heating begins with a rise of the power level to 5% of the nominal power (first cycle: 160-170°C, pressure in the second cycle: 7 - 8 atm), then to 10% of the nominal power (temperature at the entrance to the reactor: 190°C, steam pressure 12.5 atm); these parameters remain unchanged on further increase of power. The total heating time for the system is 3.5 - 4 hours; during this time, nitrogen is blown in the graphite system to remove oxygen. The parameters of the power station for 50, 75, and 100% of the nominal power are given in Table 1. On shutting the reactor, it is first cooled, by utilizing the natural loss of heat, to the temperature of water in the first cycle (110-120°C), which requires 1.5-2 hours. The cooling water is then removed from circulation and cooled; this enables the reactor to be cooled rapidly. Reliability and duration of the reactor's operation depend on the quality of the fuel element; the station works with tube type elements. The fuel is contained between two tubes of nonrusting steel (the inner is 0.4 mm thick and the outer 0.2 mm thick). This kind proved to be particularly reliable: Not a single element has been dislocated during the whole period the station has been in operation. The system of partial renewal of the fuel element is used for guaranteeing the deepest possible burning. (N. A. Dollezhal et al. reported on this at the Second Geneva

Experience from work with ...

Conference, 1958). Numerical data about the consumption are given in Table 2. Deformation of the fuel elements were checked; a deformation of 14.20 ± 0.02 mm of the element jackets was found. Experiments relating to the boiling of water in the fuel channels and determination of the hydrodynamic characteristics of the fuel elements in the reactor were started in 1956. The preliminaries were completed in September 1956, and one channel was brought to boiling operation. This first boiling channel worked for 400 hours at thermal loads of $(0.45 - 0.85) \cdot 10^6$ kcal/m²·hr (steam content 5 - 20% by weight, flow rate 250 kg/hr). As the system proved satisfactory, more channels were brought to boiling operation; in the middle of 1957 there were 70 such channels, more than half of the total. The boiling operation was characterized by the following parameters: Steam content at the exit of the channels: 5 - 25% by weight, thermal load $(0.6 - 1.3) \cdot 10^6$ kcal/m²·hr, water flow rate 0.7 - 1 m/hr at 100 atm and 190°C at the exit. Since superheating of steam constitutes one of the most important methods for increasing efficiency, experiments in this connection were carried out in the following years with a special experimental loop (Fig. 1) to study the methods of bringing the steam to a superheated state. For this, a method of

Card 3/9

S/089/61/011/001/002/010
B102/B214

Experience from work with ...

starting was perfected which requires only such equipment as is used in normal operation. During the period of transformation of the superheating operation, the superheating channel could either be closed, or it could work without cooling ("dry operation"), or with water cooling. The last named method had a number of advantages. The following starting methods were studied: Starting with continuous increase of the reactor power, starting with decrease of the reactor power, and combined methods (first the former, and then the latter but lowering the power only for about 60 - 70%). To increase the safety of the reactor, a special system was built in 1959 which prevents the escape of the gas - steam mixture into the ventilation system when the tubes of the experimental holes break down. This system "for localizing the damage due to accident" (Fig. 2) not only serves this purpose but also helps to purify the gas after the accident has occurred. The system consists of a cylindrical tank (6.2 m³) whose lower part (1.8 m³) is filled with water; in it are placed the cooling coils and special nozzles through which the steam - gas mixture streams into the water in the case of an accident. The gas is introduced in a sensitive gas container. The whole system is placed in a protective container equipped with manometers, thermometers, and dosimeters. There

1961, no. 33, 35 - 69; English summary)

TEXT:

The author describes the history of studying the comet Jacobini-Zinner and meteoric stream Draconids. The orbital elements of the comet are presented which were calculated from observations of its every appearance prior to 1959. The method of determining the elements of its every appearance are by means of which those of the Draconid stream were calculated from photographic observations carried out at various stations in 1933 and 1946. Meteor velocities were assumed to be equal to the instants of meteor observations. The moment of the stream maximum activity is determined most precisely from visual observations (with an error of

Card 1/2

The history of the...

1 - 2 min), which enables one to determine the longitude of the orbit ascending node with an accuracy of up to 2".5. Attention is drawn to necessity of allowance for deviations of points of observation from the ecliptic plane. The correction in ascending node longitude for this deviation amounts to about 10" and is calculated by the formula:

$dL = \frac{P_0 \cdot \alpha}{R} \cos \beta_0 \sin (\lambda_0 - L) - \operatorname{ctg} \beta \sin (\lambda - L) \times \left(B + \frac{P_0 \cdot \alpha}{R} \sin \beta_0 \right)$,
where $P_0 = 8''.80$ is equatorial horizontal parallax of the Sun, $\rho_0, \beta_0, \lambda_0$ are geocentric coordinates of the observational station, R, B, L are heliocentric coordinates of the Earth's center, β, λ are geocentric coordinates of the radiant.

AUTHORS: Pechenkin, A. L., Yevdokimova, A. I., Sorochenko, A. A.

TITLE: Plastics (Etrols) on the Basis of Cellulose Esters

PERIODICAL: Plasticheskiye massy, 1960, No. 3, pp. 2-8

TEXT: The authors report on their study of compositions and applications of etrols. 1) Acetobutyrate cellulose etrol (ABCE). Resistance to water and frost, and compatibility with plasticizers increase with increasing content of butyryl groups in this ester, while its heat resistance decreases. The physicomechanical characteristics as dependent on the plasticizer used are given. Hence, the authors conclude that, among all plasticizers studied, dibutyl sebacinate offers the strongest resistance to frost. Triphenyl phosphate gives a higher hardness and strength in static bending. Dioctyl phthalate gives better characteristics of resistance to heat and toughness. The following plasticizers were also tested: dibutyl phthalate, dioctyl sebacinate, tricresyl phosphate, dibutyl adipinate, and E4-242 (YeD-242). Salol, as well as mixtures of resorcinol dibenzoate with 1,3,5-tri tertiary butyl phenol

Esters B016/B054

(П-23, P-23), and of salol with P-23, proved to be the most efficient stabilizers. Besides, the authors studied: p-octyl phenol, p-amyl phenol, resorcinol disalicylate, and resorcinol dibenzoate. The authors give the physicomechanical characteristics of four ABCE types developed by NIIIPP (Scientific Research Institute of Plastic Products): АБЦ-45-20 (ABTsE-45-20) and АБЦ-38-20 (ABTsE-38-20), both for lining steering wheels and for the production of small workpieces; АБЦ-38-12 (ABTsE-38-12) and АБЦ-45-8 (ABTsE-45-8) for the production of thin-walled workpieces without reinforcement and larger parts of motor vehicles in temperate and tropical climates. This substance is also suited for the radio industry, for the production of musical instruments, spectacle frames, incombustible toys, and the like. 2) Acetopropionate-cellulose and tripropionate-cellulose etrols, as compared with ABCE plastics, have better mechanical properties, resistance to heat and water, can be easily dyed with various colors, and have a more decorative look. Best plasticizers for them were: mixtures of dibutyl phthalate and dioctyl phthalate. The following types were tested: АНЦ-48-30 (APTSE-48-30); -48-15; -33-30; -33-20; ТНЦ-64-20 (TPTSE-64-20), and -64-15. They are suited for the production of motor-vehicle parts, door handles, radio

and telephone parts. Among ethyl cellulose esters of the types ЭИ (EP) and ЭИТ (EPT), molded, and ЭЛ (EL) as well as ЭИТ (ELT), centrifugally cast, EL and EP are intended for use in temperate and cold climates, the others for tropical climate. They can be easily dyed with various colors. On account of their valuable properties, they are recommended for high-duty workpieces (motor-vehicle parts). The authors mention the following collaborators: M. V. Gubachev, G. A. Balayev, Ye. N. Matveyeva, F. F. Meshcherova, A. A. Kozodoy, V. I. Gribkova, and V. L. Gusakova. There are 8 figures, 6 tables, and 11 references: 3 Soviet, 1 German, 6 US, and 1 British.

"Zhur Obshch Khim" Vol XVII, No 3

It was found that the degree of swelling of the films in water solutions was considerably higher than in water alone, and that the constituents of the softening bath were absorbed by the films in proportions differing from those in which they are present in the bath.

TITLE: The Removal of Impurities Accumulated in Zinc Electrolyte (Ob
osvobozhdenii tsinkovogo elektrolita ot nakaplivayushchikhsya
primesey)

PERIODICAL: Tr. soveshchaniya po metallurgii tsinka, 1954. Moscow,
Metallurgizdat, 1956, pp 151-152

ABSTRACT: In order to free the electrolyte of a number of admixtures
which accumulate in it, a portion of it is periodically withdrawn
from the hydrometallurgical cycle. Solutions rich in admixtures
may be utilized in the production of lithopone; as the amount of
admixtures diminishes, the solutions may be utilized in the pro-
duction of ZnSO₄ or in the manufacture of basic Zn sulfate or Zn
oxide and ammonium sulfate.

AUTHORS: Yevdokimova, A.K., Migina, A. I. and Tseydler, A.A.
TITLE: Treatment of Zinc- and Tin-oxide containing dusts with sulphuric acid. (Sernokislotnaya pererabotka vozgonov, soderzhashchikh okisi tsinka i olova).

PERIODICAL: Tsvetnyye Metally, 1957, No. 9, pp.25-31 (USSR).

ABSTRACT: The authors describe experiments carried out by the Gintsvermet organization on the treatment with sulphuric acid solutions of dusts containing zinc and tin oxides extracted from fumes produced: 1) during the smelting of secondary copper; 2) during the fuming of slags obtained from 1); and during the fuming of tin-production slags. They tabulate the compositions of the dusts (Tables 1 and 2) and give results of experiments on leaching with sulphuric acid of dusts calcined at 500, 700 or 900° or not calcined and of comparative experiments with pure oxide mixtures of various compositions. The behaviour of the dust was found to depend on their source. A further series of experiments was carried out only with the dusts obtained during fuming, in which the dusts were treated with concentrated sulphuric acid the sulphatized product being leached with water; sufficient acid was added to sulphatize the zinc and lead or the zinc, lead

Card 1/2

136-9-5/14

Treatment of Zinc- and Tin-oxide containing dusts with sulphuric acid.

and tin. The zinc-tin compounds were found to break down under the action of the concentrated acid. Finally, the authors give an account of their investigation of the combination of zinc and tin oxides calcined together in various proportions for four hours at 900 or 1200°C: stable compounds of the type SnO_xZnO were formed at 900°C, the rate of the reaction rising with increasing temperature and Sn:Zn ratio.

There are 3 figures, 5 tables and 2 Russian references.
