trap and produce intense beams of fast neutral hydrogen or deuterium atoms. On the basis of cryogenic methods developed at the author's institute, it is proposed to use as charge-exchange targets supersonic jets of gases such as  $\text{CO}_2$ ,  $\text{N}_2$ ,  $\text{O}_2$ , Ar, and  $\text{H}_2$  flowing in vacuum and completely condensed on a cooled surface (78K). The experiments reported were made with carbon dioxide. The main parameters of a supersonic jet of this gas are first derived, after which the experimental setup, the test procedures, and the results are described. The investigations give grounds for assuming that in spite of the fact that the gas was not fully condensed and that an inverse flux of  $\text{CO}_2$  molecules was observed, the use of carbon dioxide as a charge-exchange medium is feasible particularly if the purity of the gas and the pumping-on rate are increased. The possibility of the maximum amounts of carbon dioxide that can be frozen on the condenser and the possibility of constructing a closed-cycle system are also discussed. Future experiments are planned at ascertaining the possible use of other gases and deeper cooling. "The authors thank

ACCESSION NR: AT4036072

volume of the trap against the entry of jet molecules by an "absolutely black" channel, constituting a tube cooled to low temperature. The experiment demonstrated the feasibility of the use of hydrogen cooling for the development of supersonic gas target jets, and that no additional technical problems arise in this connection; in fact, the vacuum can be improved somewhat. The experiments have also shown that tubes which are cooled with liquid hydrogen or liquid helium are practically "absolutely black" to the molecules of all gases with sufficiently low vapor tension at the corresponding temperature. It is suggested that in conjunction with effective pumping methods this method of protection will find application in thermonuclear and other devices where large pressure drops are necessary in high or superhigh vacuum. TITLE: Investigation of a supersonic carbon dioxide jet as a target for ionic charge exchange

SOURCE: Zhurnal tekhnicheskoy fiziki, v.33, no.3, 1963, 973-981

TOPIC TAGS: high energy neutral beam, charge exchange target, CO<sub>2</sub>, H, hydrogen

ABSTRACT: As part of a continuing program directed toward obtaining beams of neutral hydrogen and deuterium atoms, the charge exchange of a low energy proton beam and a supersonic carbon dioxide jet was investigated. The jet beam was produced in an arc source of the type described by J.Kistenaber and P. Hous Dasher (ZfP, 10, 103, 1951); it was focused by a three element electrostatic lens and emerged through a 1 mm aperture. The beam current was 100 mA and the proton energy was varied from 10 to 25 keV. After neutralization of the CO<sub>2</sub> jet, neutral charge exchange and ionization cross sections were measured within a Faraday cup. Also, both the beam current and the jet flow were measured and the fraction of neutral atoms present was determined.

TITLE: Ionization of fast hydrogen atoms in a strong

field. Abstr. Zh. Fiz. Magnitnyye iovnyye (Magnitnyye iovnyye)

TA: strong magnetic field; ionization; plasma physics; atom; fast particle

Abstract: Results are given from preliminary experiments on the ionization of fast hydrogen atoms with an energy of 100 eV by a laser beam with an intensity of  $10^{12}$  W/cm<sup>2</sup>. The results are reported in Nuclear Fusion Supplement 1977, part 1, p. 10. The ionization of fast atoms penetrates through the laser field. In this paper we measured directly the ionization of fast hydrogen atoms passing through a laser field. We used two copies of lenses with diameters 10 cm. The results were as follows:

1 24047-00

AEC NO. AT66-28842

... a battery of capacitors. The buildup time for a field of 10 kilogauss in the center of the gap between the plates was about 100 microseconds. A reduction in the field at a radius of 1.5 centimeters from the central hydrogen atoms was produced by charge exchange of the beam with a jet of carbon dioxide frozen on a surface. The exchange target was 0.9 meters from the axis of the main field. The particles ionized in the central region of the field (1.5 centimeters) was determined by simultaneously measuring the ion current from the central collector and the ion current through the central collector with respect to the beam and to the two other collectors.

neutral drift in the nonhomogeneous field only for the case of 10 kilogauss. In the case of weaker fields, some of the ions are incident on the input and output collectors and when the field is low (11-15 kilogauss) not one of the particles ionized can reach the central collector. A curve is given showing the ionization in the central region of the field as a function of field strength. Between this curve and the data in the literature on ionization for individual levels of the hydrogen atom with a given  $n$  it is shown that atoms with  $n = 9$  are ionized in magnetic fields of 32 to 51 kilogauss. Ionization of atoms with  $n = 8$  takes place in fields. Even in extremely strong fields, a continuous current is observed in  $H$ . In some experiments the current through the output collector than could have been expected for residual gas ionization. A considerable number of hydrogen atoms may have been excited to the mean free path of several centimeters in strong magnetic fields. Part 1 has 3 figures.

AW UkrSSR. Magnitnyye Iovushki (Magnetic jets) 1977-1978

supersonic flow, hydrogen plasma, cryogenic, vacuum

ABSTRACT Experiments are conducted on the use of cryogenic gas and a supersonic jet of hydrogen on the basis of the supersonic flow of gas in generating supersonic gas jets of CO<sub>2</sub>, Ar and H<sub>2</sub>. From a technical standpoint since the surface on which the jet is directed is a solid medium. Preliminary experiments have shown that the jet is stable even when the thermal loads are high. The heat flux at the wall is sufficient for hydrocarbon evaporation. The maximum jet thickness is 0.5 cm. Hydrogen jet velocity is 45-50 cm/sec. A curve is given showing the contact number as a function of the hydrogen flow.

which is described in this work. Magnetic fields of 100 kG were attained by cooling multilayers (1000 turns) of 0.5 mm diameter wire to 4.2 K. Two-stage cooling with liquid nitrogen followed by liquid helium made it possible to energize the coil twice at the same current. The coil construction and the multilayer construction are described in detail. The inductance of the coil was determined to be 0.8 H and 0.2 H ohm at low current. The coil with variable separation along their axis can be used to produce a magnetic field configuration normally forming a working volume of a very uniform field. The entire assembly was placed in a vacuum chamber. A neutral injection experiment is performed. Very high vacuum pumps provide the necessary vacuum conditions. Orig. art. has 10 pages.

TITLE: A new method for pumping out hydrogen

Journal: Journal tekhnicheskoy fiziki, v. 36, no. 1, 1966

Keywords: vacuum pump, hydrogen, carbon dioxide, absorption

It has been found that a layer of carbon dioxide efficiently absorbs hydrogen and that this property can be used in a vacuum pump. In a separate paper they also report on the use of carbon dioxide. A 22.7 cm diameter spherical vessel had been pumped down and cooled to 20 K. The pressure was about  $2 \times 10^{-7}$  mm Hg. A layer of carbon dioxide was measured at a thickness of 0.1 mm. The equilibrium pressure of hydrogen in the condensed carbon dioxide was measured. The concentration of hydrogen in the gas phase was 1% the equilibrium pressure at 29.4 K.

Card 1/2

I 21755-66

ACC NR AIN04-11

was 4.5% the equilibrium pressure was  $1.2 \times 10^{-6}$  mm Hg. It increased rapidly with decreasing temperature, and for a temperature of 14°K it was  $5 \times 10^{-7}$  mm Hg. The measured CO<sub>2</sub> surface was about 20 liter/sec at low pressures and diffusion of the absorbed hydrogen in the condensed layer when the CO<sub>2</sub> layer was ~8 microns thick equilibrium was reached. Condensed layers of alcohol, benzene, and acetone were found but less efficiently than carbon dioxide, condensed layers evinced little pumping action. Orig. art. has 3 figures.

TITLE: VGL-2 cryogenic magnetic trap

SOURCE: Atomnaya energiya, v. 21, no. 2, 1966, 130-131

TOPIC TAGS: <sup>MAGNETIC TRAP DEVICE,</sup> magnetic trap, hydrogen plasma, deuterium, plasma heating, plasma injection, cryogenic liquid cooling/VGL-2 magnetic trap <sup>DEVICE.</sup>

ABSTRACT: Since one of the means of producing a hot plasma is to inject intense beams of fast neutral hydrogen or deuterium atoms into a magnetic field, where they can be ionized, the authors describe the processes accompanying the filling of a small magnetic trap in which a strong magnetic field is produced. (Fig. 1) The trap differs from earlier designs in that the strong magnetic field up to (105 kG) is produced by a copper coil cooled with liquid nitrogen, which is also used to cool the outside of the vacuum chamber and thus permits a vacuum as low as  $\sim 5 \times 10^{-10}$  Torr to be maintained in it. An Ardenne type source is used for the hydrogen-ion beam, the charge exchange being in a supersonic CO<sub>2</sub> stream condensed on a surface cooled to 20.4K. The fraction of the neutral beam ionized in the wording region of the chamber

TITLE: Investigation of the sorption of hydrogen and neon on solidified gases

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 36, no. 11, 1968, 2042-2050

TOPIC TAGS: sorption, hydrogen, neon, solid state, gas, carbon dioxide, alcohol, benzene, water, nitrogen, argon, high vacuum pump, absorption pump

ABSTRACT: This paper is devoted mainly to an experimental investigation of the sorption of hydrogen on solid carbon dioxide at temperatures from 14 to 20° K. The sorption of hydrogen and neon on carbon dioxide, alcohol, benzene, water, nitrogen, and argon was also investigated. The sorbent was condensed on the surface of a 22.5 cm diameter copper sphere cooled with liquid hydrogen and mounted within a 100 liter vacuum chamber. In some of the experiments the working volume of the chamber was shielded from the walls by a surface cooled to 78° K. When the shield was employed a limiting vacuum of  $2 \times 10^{-9}$  torr could sometimes be achieved. The sorbent was admitted in gaseous form and condensed on the cold sphere before the shield was cooled. Measured quantities of the sorbate were subsequently admitted and the consequent pressure changes were observed with Pirani and ionization gages. The quantity of sorbed hydrogen at a given temperature and pressure was found to be proportional to

Card 1/2

UDC: 537.625; 541.183

ACC NR: AP6036036

the quantity of carbon dioxide sorbent. Sorption isosteres were recorded and sorption isotherms were calculated from them. The isotherms were similar in shape to Langmuir isotherms for monomolecular adsorption but correspond to large areas of the sorbent. It is concluded that at saturation (not reached in the experiments) there is one molecule of hydrogen for every two or three molecules of carbon dioxide. The heat of sorption of hydrogen on condensed carbon dioxide was 1400 cal/mole at a sorbed hydrogen concentration of 0.4 mole percent and decreased to 700 cal/mole at a concentration of 11.5 mole percent. The heat of sorption of neon on carbon dioxide was somewhat lower than that of hydrogen. Of the other sorbents investigated, those with complex polyatomic molecules were also efficient sorbents, and nitrogen and argon were not. Pumping speeds and sticking probabilities were obtained from the observed rates of pressure decrease. The maximum sticking probability of hydrogen on carbon dioxide at 14° K was 0.45, and the sticking probability decreased very slowly with increasing concentration of sorbed hydrogen. On carbon dioxide at 20.4° K the maximum sticking probability was 0.42 for hydrogen and 0.1 for neon. It is concluded that the investigated sorption process is physical in nature and that the hydrogen and neon are sorbed on the same centers, the difference between their sorption isotherms being due only to the difference between their heats of sorption. The authors will discuss in another paper the application of the investigated sorption process to pumping of hydrogen and neon in ultrahigh vacuum systems. The authors thank Ye.S. Borovik for discussions and for advice concerning the preparation of the paper. Orig.art. has: 7 formulas and 7 figures.

TITLE: Mastering production of pipes from steel 12Kh6S2M

CITED SOURCE: Sb. Proiz-vo trub. Vy\*p. 11. M., Metallurgizdat, 1963, 7-9

TOPIC TAGS: pipe, pipe production, rolling, heat treatment/12Kh6S2M steel

TRANSLATION: In the development of production technology of pipes from steel 12Kh6S2M there was investigated metal of pipe billets of composition (%): C, 0.12; Si, 1.53; Cr, 5.12; Mn, 0.38; Mo, 0.70; Nb, 0.25; Ni, 0.25; S, 0.014; P, 0.015. Billets had diameter 85 millimeters and length 900-1000 millimeters. Experiments for piercing were conducted on the laboratory piercing mill of the Ukrainian Scientific Research Institute of Pipes. Rolls of the mill had in pressing a diameter of 140 millimeters and angle of entrance and output cones of 3°30'. There were rolled test pieces of diameter 35 millimeters and length 90

Card 1/3

ACCESSION NR: AR4041538

millimeters. For comparison there were pierced also test pieces of Steel 10. During rolling they measured the load on the motor of the piercing mill and pressure of metal on the roller; temperature of heating was determined by a control piece with a thermocouple. During pressing in the 16% press, a cavity was uncovered at all rolling temperatures; with increase of temperature dimensions of the cavity decreased, which corresponded to results of twisting tests. During pressing, of 10%, openings of the cavity were not observed. Proceeding from given data, the temperature of piercing was selected within 1220-1250°. Rolling of pipes was produced on automatic installation 140 with a roller-type piercing mill. Before piercing, billets were heated in a Hoffmann kiln for 50-60 minutes. During piercing, adjustment of the piercing mill was the following: diameter of rollers 738 millimeters distance between rollers in narrowing: 76 millimeters, between straightedges: 83 millimeters; diameter of mandrel: 68 millimeters; advancement of blade of mandrel beyond narrowing: 37 millimeters; diameter of housing: 93 millimeters; thickness of wall of housing: 11 millimeters; pressing before blade of mandrel: 5.3%, calibration of rollers symmetric with angle of conicity: 3°30'. Load on mill motor 850-950 kilowatt. On automatic mill, housings were rolled in gauge of 88 millimeters applying mandrels 70 millimeters in diameter. During the first pass and 72 millimeter during the second pass. On the rolling mill pipes were rolled up to a diameter of 96 millimeters, after which they were

Card 2/3

ACCESSION NR: AR4041538

calibrated to finished dimension 89 x 8 millimeters and subjected to straightening. Investigation of branch connections cut from finished hot-rolled pipes showed that their metal had a martensite structure and was characterized by the following properties:  $\sigma_b$ , 143 kg/cm<sup>2</sup>;  $\sigma_s$ , 123.5 kg/cm<sup>2</sup>;  $\delta$ , 6.5%,  $a_k$ , 9.3 kg/cm<sup>2</sup>; and hardness 302H<sub>p</sub>. Intermediate heat treatments of pipes in the process of cold rolling consisted in annealing at a temperature of 760-780° which ensured removal of work hardening, preservation in the metal of the structure of granular perlite and restoration of mechanical properties. On the basis of conducted investigations there was developed the technology of production and prepared an experimental lot of boiler tubes of brand 12Kh6S2H steel.

TITLE: Manufacture of tubes from new ferritic martensitic heat  
resistant steels

SOURCE: Stal', no. 3, 1964, 258-263

TOPIC TAGS: heat resistant steel, steel tube, ferritic martensitic  
steel, tube rolling

ABSTRACT: The authors report on techniques developed in recent years  
by the Ukrainskiy n.-i. trubny\*y institut (Ukrainian Tube Research  
Institute) in cooperation with tube factories in Pervoural'sk and  
Nikopol for hot rolling and heat treating of tubes made from 9 new types  
of steel, all of which contain 10-14% Cr and additions of V, Mo, Nb,  
and W. The AC temperature was in the range of 810-830C; ferrite  
grain growth was noted above 1100C; piercing temperatures varied from  
1090 to 1200C. Ductility at high temperatures was found to depend on  
the content of free ferrite, and piercing of tube billets presented no

Card 1/2

ACCESSION NR: AP4019481

difficulties at a content of 50%. At 15—20% ferrite hot tears, cracks, and laps were formed. Annealing of hot-rolled and reduced tubes at 770—780C imparts a structure of granular pearlite and the mechanical properties needed for further cold reduction. Metal consumption for almost all steels, including machining, proved no higher than those for similar pipes of stainless steels in current production practice. "Engineers N. S. Kirvalidze, R. A. Prudkova, N. N. Pil'nikova, L. S. Rakhnovetskiy, I. S. Pechennikova, and others took part in the work." Orig. art. has: 8 figures and 2 tables.

TOPIC TAGS: steel pipe, pipe rolling, austenite steel, ma-  
steel, stainless steel pipe, steel phase transformation

ABSTRACT: Phase transformations of austenite into martensite  
less steel during cold deformation has been taken into account  
the technology of hot and cold-rolled pipes. The martensite  
formation of this steel lies around 150C and the range of transition  
to austenite is between 500 and 700C. Mass production of this  
steel pipe is quite possible if the raw material is free of  
nitrides and carbonitrides). The above steel type (AISI 301) can  
be having a 5% lower Cr content substituted by 3% Si. It shows

Card 1/2

ACCESSION NO: AFDP02974

test: that its ductility changes during hot deformation and stable austenite to martensite takes place during cold deformation. Hot rolling of forged 90 mm diameter billets are described. Accumulations of nitrides were observed. Cut-out samples were strength tests at various temperatures and the content of the phase was determined. On the basis of these tests, the following is recommended. First passes of cold rolling are to be done after heat treated at 1050-1100C. This steel has a tendency to crack by cold working after heat treatment. After removes this hardening. Despite martensite formation, cold rolling was satisfactory and drawing was also satisfactory except for cracking. There is accumulation of nitride impurities. (The N. Spaul and J. in the work." ABSTRACT: The authors describe their experience with three types of information-search systems (ISS) which were developed by inventors, efficiency experts, and innovators of the USSR. The development of the ISS began in October, 1964. All three ISS employ punched cards and machine-sorter punched cards. The ISS are developed on the basis of a single type of information notation, dealing with the technical descriptions of some of the enterprises of a technical-information newsheet. Both the ISS employing the machine-sorter cards used a unified search notation code system.

**TITLE:** The absorptive capacity of oils used for the absorption of benzole hydrocarbons

**PERIODICAL:** Koks i khimiya, no.3, 1963, 35-37

**TEXT:** A method of evaluating the absorptive capacity of oils used for the absorption of benzole hydrocarbons in the coking industry is proposed. The amount of benzene adsorbed per hour at a difference of its partial pressure of 1 mm, is taken as a criterion of the absorptive capacity. Thus the amount of absorbed benzene is related to the whole contact area of a standard laboratory absorber. This criterion is supplemented by the amount of the oil's fraction distilling up to 230 °C. The determination is done by passing a known volume of purified coke oven gas, to which a known volume of gaseous benzene is added, through a laboratory absorber filled with the oil investigated. The absorbed benzene is distilled off using a standard laboratory rectification column, weighed and recalculated for a difference of partial pressures of 1 mm. The formula used is

Card 1/2

$$A = Q/\Delta P_{\text{mean}}$$

The absorptive capacity of oils ...

S/068/63/000/003/001/003  
E071/E136

where: A - absorption capacity of oil, g.hr/mm; Q - the amount of absorbed benzene, g/hr;  $\Delta p_{\text{mean}}$  - mean logarithmic difference of partial pressures, mm Hg;

$$\Delta p_{\text{mean}} = \frac{\Delta p_1 - \Delta p_2}{2.303 \log \frac{\Delta p_1}{p_2}}; \text{ where } \Delta p_1 = p_1 - p_2';$$

$\Delta p_2 = p_2 - p_1'$ ; where:  $p_1$  - partial pressure of benzene in the gas entering the absorber;  $p_2$  - the same, leaving the absorber;  $p_1'$  - vapour pressure of benzene vapour over oil leaving the absorber;  $p_2'$  - the same entering the absorber. Experimental data determined by this method are given for a number of fresh and used oils. There are 1 figure and 2 tables.

Abstract: This collection of articles is intended for engineers and technicians designing developing and operating electrical apparatus and is concerned with electric contact resistance. It may also be useful to scientific research laboratories and universities.

CONTENTS: This book contains reports delivered at the Electric Contacts Conference held in Moscow in November, 1975. These papers cover physical processes occurring during manufacturing in electroforming, methods of designing and testing electrical contacts, production and characteristics of contact materials. During discussion of the last but a somewhat technical seminar on the production of electrical contacts and materials, Academy of Sciences, USSR) participants discuss design problems and scientific problems of electric contacts, such as the components of electric apparatus primarily influencing the reliability of electric systems, especially the control systems. Their physical, chemical, mechanical and chemical processes were still not been well analyzed. References are given at the end of most of the reports.

III. PRODUCTION AND CHARACTERISTICS OF CONTACT MATERIALS

Bobokov, I.E. Institute of Automation and Telemechanics, Academy of Sciences, USSR) The author describes the production and properties of contact materials used in this investigation. He gives the results of the study as well as the characteristics of the most used composition.

Shchegolev, I.S.A. (SII - Aero приборостроения) Near Resistance of Tungsten Contacts The author describes the investigation of cut tungsten contacts relative to the effect of internal structure and method of production on resistance to wear.

Shchegolev, V.V. and Povolozhskiy, M.D. (Mashinostroyeniye) Institute of Technological Processes, Academy of Sciences, USSR) The author describes the investigation of the properties of contact materials for the production of apparatus for the space program. A description of apparatus for the space program is presented.

Bobokov, I.E. (Institute of Automation and Telemechanics, Academy of Sciences, USSR) Alloys of Precious Metals as Electric Contact Materials for Very Low Voltages and Currents The author analyzes the composition and resistance to corrosion and mechanical wear of various alloys composed of metals.

Krillom, G.S. Alloy for Electric Contacts With Small Contact Resistance The author specifies the standard alloy for sliding contacts operating with small currents and contact pressure. She compares three alloys from the point of view of reliability, corrosion susceptibility, contact resistance, mechanical and electrical characteristics, and cost.

VINAROVA, YE. Application of New Materials for Sliding Contacts in DSP Systems (Self-synchronizing Systems) The author specifies the new borist standard sliding contacts, describing their characteristics and application.

VINAROVA, YE. Survey of Experimental Research on Contact Materials From Precious Metals This is a brief report on borist standard palladium alloys T6-40, T6-50, T6-10, and T6-15.

VINAROVA, YE. State of the Production and Standardization of Contacts and Contact Materials From Precious Metals The author describes the developments obtained in the production of borist standard alloys of precious metals. Considering the amount of contact and conductor types, she suggests the opinion that a standardization of types is necessary. He suggests the creation of a special organization for the coordination of scientific research activities on contacts of all kinds and the standardization of metals and alloys used in these.

TITLE: Elements of Digital Computers Based on the Principle of  
Integration of Voltage Pulses

PERIODICAL: Avtomatika i telemekhanika, 1960, Vol. 21, No. 8,  
pp. 1165-1172

TEXT: Reference is first made to circuits of semiconductor units based on the principle of integration of voltage pulses (Refs. 1 and 2). The mode of operation of these circuits is briefly explained. At present, two types of units are being developed, which are based on this principle. In the first type, a preset number of pulses is stored in an integrating core. After the end of integration, a signal is released at the output of the integrator. These units are used for frequency dividers, counters, etc. The second type is characterized by the fact that not more than three voltage pulses can reach the input of its integrating cores, and that there is a certain signal power at the output, according to the quantity stored. This type is used for the construction of summators. The circuit diagram of an

integrator is reproduced in Fig. 2. Such a circuit diagram was first published in 1955 (Ref. 1). The mode of operation of this integrator is briefly explained. Figs. 3 and 4 illustrate two basic circuit diagrams of this integrator. At present, integrators with five and ten stored pulses are being developed. Advantages of the integrators under consideration are their high efficiency (concerning the number of units) and the lack of generators of strong displacement pulses. Disadvantages of these integrators are the increased requirements to be met in the sorting of triodes and the delay of the output signal with respect to the input signal. Next, the author explains the method of constructing summators based on the principle of integration of voltage pulses, which was published in 1958 (Ref. 3). Fig. 5 shows the main structural elements, i.e., the integrating magnetic element and the selective circuits. Two circuits - a four-cycle and a two-cycle summator - are studied (Figs. 9 and/or 10 and 11). These summators were tested satisfactorily. They showed a stable operation between  $-40^{\circ}\text{C}$  and  $+55^{\circ}\text{C}$  and also when the commutator voltage was changed within the range  $-20 - +27$  per cent of the rated value. The small number of units is considered to be the main advantage of the above-described summators. There are 12 figures and 3 references: 1 Soviet and 1 US.

2368. A. P. Yufin, Motion of a heterogeneous liquid in horizontal non-aerated steel pipes (in Russian), *Izvestiya, Uchebno-Nauk. Ser. 8*, 1130-1139 (Aug. 1989).

Results are reported on experimental pumping of sand-water mixtures through a system of pipes connected in series and having diameters of 150, 200, 250, and 300 mm. Pipes of five different grain sizes, ranging from 0.25 to 7.35 mm, were used. The data obtained agreed with those of O'Brien only at velocities higher than velocity which is critical in respect to settling out of particles. For lower velocities, a coefficient correcting conventionally computed gradient losses for difference between discharge density and actual density was determined as a function of pipe diameter, size of solid particles, consistency of mixture, and its average velocity. It is suggested that subcritical velocities may be more reasonable for field use. Note typographical error on fig. 8: in lower half of diagram for  $d$  read  $D$ . This diagram summarizes results of supplementary tests on critical velocities.

**TITLE:** Research Work in the Field of Mining Hydraulic and  
Pneumatic Transport

**PERIODICAL:** Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh  
nauk, Metallurgiya i toplivo, 1959, Nr 3, pp 180-183 (USSR)

**ABSTRACT:** This is a brief review of the state of the utilisation  
of hydraulic and pneumatic transport of mined minerals  
in various countries and of the main directions of the  
research work on the subject carried out by the  
Institute IGD of the Academy of Sciences of the USSR.  
Main points: 1) Analysis of technico-economic  
efficiency of application of hydraulic transport and  
the field of its application. It was established that  
long range transportation of materials of a size above  
6 - 3 mm is at present uneconomical. The field of  
application of hydraulic transport of coal at distances  
of 90 - 50 km is governed by conditions of wet  
beneficiation or the removal of water from deposits.  
2) Studies of basic hydraulic and kinematic characteristics  
of streams of hydromixtures (the relative velocities of

Card 1/2

Research Work in the Field of Mining Hydraulic and Pneumatic Transport

movement of particles, starting, free and inhibited fall etc). 3) Investigations of hydraulic transport of coal and other minerals in horizontal and vertical pipes of a small and large (400 mm) diameter.

4) Development of methods of designing hydraulic transport on the basis of a single semiempirical theory.

5) Investigation of the pulsation characteristics of a stream of hydromixtures. 6) Development of control and measuring apparatus for research and industrial purposes.

7) Investigation of hydrotransport of minerals under industrial conditions (investigations were carried out in the Donets basin, some experimental work was carried out on the determination of parameters of hydraulic transport of ores of 0.3 - 0.4 m in size).

8) Development of some new types of small scale pneumatic installations (in the Kuznetsk basin). In the appendix some apparatus and installations are briefly outlined and illustrated. There are 3 figures.

TITLE: Radioactive Densimeter for Gravity Control on Pipelines Simultaneously Carrying Various Batches of Petroleum Products (Radioaktivnyy plotnomer dlya izmereniya plotnosti nefteproduktov v truboprovodakh pri posledovatel'noy perskachke)

PERIODICAL: Neftyanoye khozyaystvo, 1958, <sup>36</sup> Nr 10, pp 58-62 (USSR)

ABSTRACT: Radioactive densimeters for measuring the gravity of the various petroleum products simultaneously carried by pipelines have already been designed in the United States [Ref 1] and in the Soviet Union. The GP-1 densimeter, designed by the VNIINP Institute and described in the literature [Ref 2], had a number of defects which were eliminated in the PZhR-2 densimeter (Fig. 1) designed by the NII Teplopribor. The PZhR-2 Model consists of a radioactive source mounted on a disc and rotated by a synchronous motor. The gamma rays from the source alternately pass through the test fluid and the compensating wedge and hit a scintillation counter. The electric impulses emerging in the counter are summed up on the integration cell from which a sinusoidal signal of unbalance is obtained. The signal of unbalance is amplified by an amplifier and with the aid of a phase-sensitive

Card 1/2

SOV/93-58-10-13/19

## Radioactive Densimeter for Gravity Control (Cont.)

instrument rotates a reversible motor which shifts the compensating wedge until the streams of radioactive rays passing through the test fluid and the compensating wedge are balanced. The compensating wedge is shifted simultaneously with the core of the induction coil which masters the telemetric system of the secondary instrument. The distance the compensating wedge is moved from the neutral position is directly proportional to the variation in the density of the petroleum product. (Fig. 2) shows how a PZhR-2 densimeter is employed on a pipeline of 150 mm in diameter carrying three different petroleum products. In this case the data were recorded by an EPID-03 type secondary instrument, but when it is necessary to record the change in density with respect to time the EPID-03 unit must be replaced by a DSR instrument. A record of change in density with respect to time is shown by (Fig. 3) and the percentage of error is given in (Table 1). The authors conclude that the PZhR-2 densimeter operates within an accuracy of 0.5 percent (0.005 g/cu cm) and that the accuracy can be improved further by stabilizing the intensity of the electric feed. The PZhR-2 unit can be employed on pipelines of 100-500 mm in diameter. It will be produced serially in 1959. There are 3 figures, 1 table, and 2 references, 1 of which is Soviet and 1 English.
