Cameras of Debye-Scherrer Type.  
Proszkowe kamery rentgenograficzne typu Debye-Scherrer.  
(Prace Inst. Metalurgii No. 2), Katowice, 1952, PWT,  
7 pp., 12 figs.

The principal features of a good X-ray powder camera were reviewed. Many often contradictory demands made upon the powder camera made it necessary to prepare a camera which could satisfy all the various needs. A description and technical data are given of a camera made to the authors design. The 114.6 mm. dia. camera is distinguished by: precise fitting of film, easy exchange of collimating tubes, simple and quick centering of test places and small ray dispersion in the camera.

Determination of mullite refractoriness by the x-ray method. Z. Zetepalli. *Publicat. Ministeria Mestale*. 6, 314-31(1954) (English summary).--A new, Bragg-Brentano type, focussing camera of Z.'s design was used for recording x-ray lines. Its construction reduces the effects of partial absorption and of the nonuniformity of the sample. The novel feature is an eccentrically rotating holder which permits the exposure of a large area of the sample. The samples were ground to a crystal size of 1  $\mu$ . As a reference material 10% of NaCl was admixed, and as a standard for comparison 95% pure mullite was used. The lines measured were: mullite,  $d_{111} = 2.20$  A. and NaCl,  $d_{200} = 1.00$  A. These lines have the least interference from other cryst. phases in a range 10-100% mullite. The measure of line intensity was taken with a microphotometer and was represented by the area comprised between the max. interference graph and the line of the mean blackening of the exposed film. The area was detd. by weighing the film. The estd. errors were about 14%. R. S. J.

**AUTHORS:** Nalecz, Maciej, Doctor of Engineering and Ziomecki, Henryk, Master of Engineering

**TITLE:** Magnetic Induction Meter using the hall effect

**PERIODICAL:** Przegląd elektrotechniczny, no. 11, 1960, 469 - 473

**TEXT:** This device was developed by the Zakład Elektrotechniki Instytutu Podstawowych Problemów Techniki Polskiej Akademii Nauk IPPT PAN (Electrotechnical Engineering Department of the Institute of Basic Problems and Technique, Polish Academy of Sciences) and serves for direct measurement of magnetic induction. The advantages of this device, compared to the conventional flux meter are: there is no need to move the sensor in and out of the magnetic field during measurements; the small size of the sensor itself (4 x 2 x 0.2 mm), which permits accurate point-to-point field measurements... This device is suitable for measuring magnetic induction on constant and variable fields with frequencies up to 10<sup>12</sup> cps. The author gives an exhaustive explanation of the Hall effect and its use in the new device. The article describes only principle of operation and circuitry of this device for measuring magnetic induction in constant fields

TITLE: On the polarization of radio waves which have passed through a region of a transversal magnetic field within the solar corona

SOURCE: Astronomicheskiy zhurnal, v. 40, no. 4, 1963, 633-642

TOPIC TAGS: solar microwave circular polarization, polarization change, characteristic parameter, interaction, phase integral, transversal field, Stokes lines

ABSTRACT: Solar microwave radiation consists of a chaotically polarized component and a circularly polarized component. The circular component is subject to change. The authors discuss Cohen's investigation of the polarization changes in which it was found that the characteristic parameter  $Q$  of the interaction of ordinary waves changes when  $Q$  is approximately equal to one. The authors study the interaction of ordinary waves in the plasma in a magnetic field by the method of phase integrals. The coordinate system is chosen in such a way that the transversal component does not depend upon the coordinates

Card 1/2

ACCESSION NR: AP3004318

and the longitudinal component depends only upon the z-axis. The electric field is a combination of real and imaginary parts, and the study is performed with a function which is expressed in phase integrals. The solution of the function shows that a strong interaction between ordinary and extraordinary waves can take place under the action of a transversal magnetic field only in a rarefied plasma. The solution of the function depends upon two constants in the phase integrals. These constants are invariable in regions limited by Stokes lines. The regions of Stokes lines are analyzed. Experimental measurements detected that the circular polarization amounts to only 40% for frequencies at which one wave transits totally into the other. Orig. art. has: 6 figures and 35 formulas.

TITLE: On the solution of nonlinear boundary value problems in the theory of elasticity by the method of transformation into Cauchy problems

SOURCE: Prikladnaya matematika i mekhanika, v. 29, no. 6, 1965, 894-901

TOPIC TAGS: Cauchy problem, boundary value problem, elasticity theory, nonlinear elasticity, numeric integration, digital computer, function, shell deformation

ABSTRACT: A method is described for transforming a boundary value problem in nonlinear elasticity into a Cauchy problem to allow for a direct numerical integration on digital computers. The method is applied to the problem of a shell deformed symbolically

$$A_i(u, v, w, p) = \dots \quad (i = 1, 2, 3)$$

it is required to determine a function  $\Phi(u, v, w)$  which can be expressed as a function of the loading parameter  $p$ . This can be done by differentiating  $\Phi$  with respect to  $p$  such that

2

Card 1/2

L 17837-66

ACC NR: AP6004073

$$\frac{d\Phi}{dp} - \sum_{n=1}^n \frac{\partial \Phi}{\partial C_{nk}} \frac{dC_{nk}}{dp} = 0$$

where  $C_{nk}$  are transformation constants. The above equation represents a set of linear ordinary differential equations in  $\Phi$  and  $C_{nk}$ . The above analysis is applied to the deformation of a spherical dome under uniform loading conditions. The governing equations are given by

$$\rho\psi'' + \psi' - \frac{\psi}{p} = \theta \left( \frac{2H}{h} \rho + \frac{1}{2} \theta \right) \left( \psi - \frac{T_1 a^2 p}{E h^3} \cdot \theta + \frac{a}{h} \theta_1 \right)$$

$$\rho\theta'' + \theta' - \frac{\theta}{p} = -12(1 - \mu^2) \psi \frac{2H}{h} \rho + \theta + 6(1 - \mu^2) p_0 \rho^2 \left( p_0 = \frac{p a^2}{E h^3} \right)$$

where  $\Phi$  plays the role of the integral

$$f = \int_1^p \theta dp$$

The resulting ordinary differential equations are solved numerically on the Minsk-12 digital computer using the Runge-Kutta integration scheme. Orig. art. has: 26 equations, 10 figures, and 1 table.

Ed. (title page): V.F. Kozlov, Professor and B.S. Rukhviser, Professor.

NOTE: This collection of articles is intended for physicists specializing  
in the physics of ultrasound.

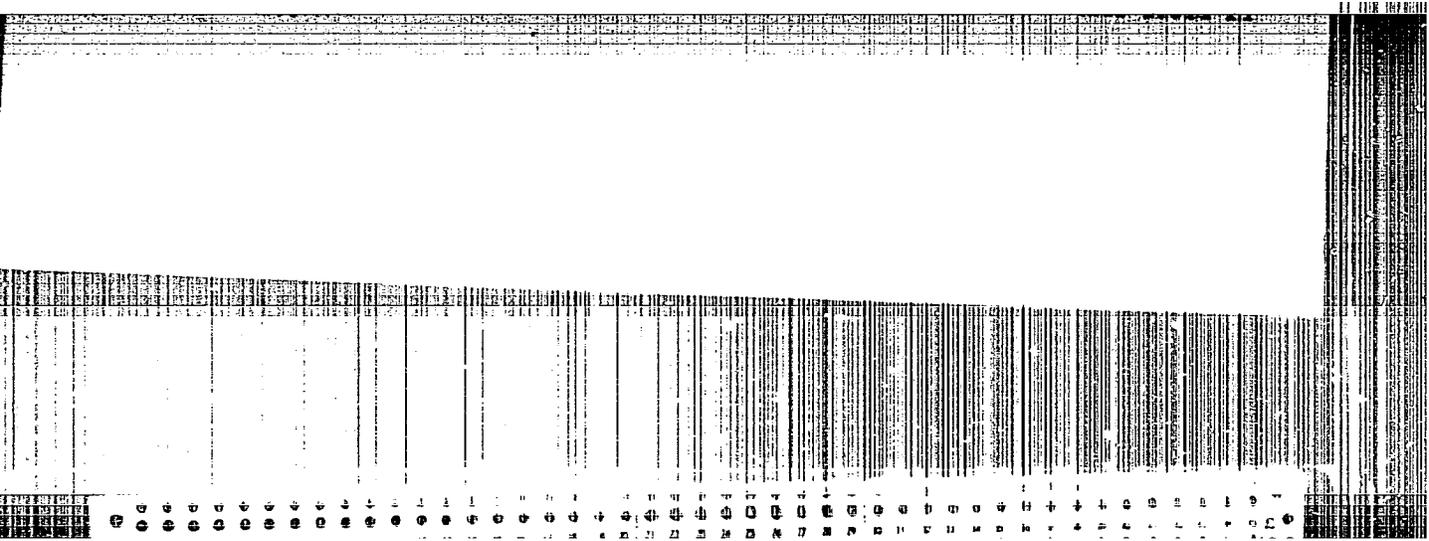

CONTENTS: The collection of articles constitutes the transactions of the VII Con-  
ference on the Applications of Ultrasonics to the Study of Materials, which was  
held at the Moscow Oblast Pedagogical Institute (Moscow Oblast Pedagogical  
articles of the collection discuss various problems in the wave mechanics of  
ultrasound, the absorption and the propagation of ultrasonic waves in  
various media, the operating principle and design of generators and receivers of  
ultrasonic waves, the speed of sound and methods for its determination. Other  
articles deal with the applications of ultrasonics to investigations of the  
properties of materials. No particularities are mentioned. References accompany  
the articles.

TITLE: Experimental basis of the method of multiple echo-pulses for the low-frequency analysis of liquids

PERIODICAL: Referativnyy zhurnal. Avtomatika i radioelektronika, no. 2, 1961, 12, abstract 2 E97 (V sb. Primeneniye ul'traakust. k issled. veshchestva, no. 11, M., 1960, 107-122)

TEXT: In measurements of the absorption coefficient of ultrasound at frequencies 1 - 6 Mc/s, the following are the factors limiting the measurement accuracy: owing to weak absorption at these frequencies, long acoustic paths are required; the measurements have to be made inside the ultrasonic beam at a point where its divergence is not yet noticeable; diffraction losses have to be taken into account. A pulse method of measuring the absorption coefficient in poorly absorbing liquids has been evolved which utilizes

Experimental basis...

multiple echo-pulses. A pulse circuitry which utilizes the existing pulse instruments is described. The duration of the transmitted acoustic pulse - 10 - 15  $\mu$  sec, repetition frequency 150 c/s. The display at the CRO screen consists of several peaks with decreasing amplitudes. Since the pulses are reflected many times both from the reflector and from the crystal (radiator), it was necessary to establish whether the reflector repeats the pulse in the same way as the crystal. The experiment showed that the quartz is not a simple reflector, but rather a transducer of acoustical energy and this fact has been taken into account in actual measurements. Two methods of measuring the absorption coefficient by means of echo pulses are described: the measurement from the n-th pulse with varying distance and the measurement with fixed spacing between the quartz and reflector. The method has been proved using well-known liquids (toluene, benzene etc.). The experimental spread of results did not exceed 4 - 6%. 7 figures. 2 references.

no. 15, Moscow, 1961, 49 - 53)

TEXT: A theoretical analysis is carried out by means of a spectral representation of a pulse. It is shown that the systematic error, introduced by the pulse method into the absorption coefficient measured by the amplitude decrease, pertaining to the signal carrier frequency, can be reduced to a value considerably less than the experiment errors, if utilizing signals of a definite length.

TITLE: Use of multiple echo pulses for the measurement of absorption of ultrasound in liquids *q w*

SOURCE: Ref zh. Fizika, Abs. 3Zh483

REF SOURCE: Tr. 1-y Mezhd. nauchn. konferentsii po primeneniyu molekul. akust. k issled. veshchestva i v nar. kh-ve. Tashkent, 1964, 181-186

TOPIC TAGS: ultrasound absorption, liquid property, acoustic damping, absorption coefficient, acoustic measurement, error minimization

ABSTRACT: A study of the multiple echo signal observed in liquids has shown that it can be used for the measurement of absorption of ultrasound in liquids at frequencies less than 5 - 7 Mcs, where other ultrasonic methods are difficult to use. Measurements were made in the 2.3 - 9 Mcs range in benzene, toluene, and ethyl alcohol, the attenuation for which was measured by many authors. Comparison with the published data has shown good agreement and permits the conclusion that this method can be used to investigate liquids with absorption coefficients  $(3 - 4) \times 10^{-3} \text{ cm}^{-1}$ , which is one order of magnitude lower than the values that can be handled by the usual pulse methods, and corresponds on the high-frequency side to values which are amenable to measurement with the aid of the reverberation method. The measurements were made with an x-cut quartz of 3.5 cm diameter. By increasing the quartz dia-

Card 1/2

I. 04088-67

ACC NR: AR6023296

meter it is possible to broaden the frequency range. The measurement error decreases by a factor  $n$  compared with the error of the usual pulse method ( $n$  is the number of counted pulses). The measurement accuracy is 6 - 8% and increases with increasing frequency and attenuation to 3 - 5%. The path traversed by the pulse can amount to several meters, which greatly exceeds the Fresnel zone; if it is assumed that it is simply reflected from the reflector and from the receiver, then the correction for the divergence of the beam gives a value which is incompatible with the attenuation-measurement results. The authors therefore propose that re-radiation (re-broadcast) of the ultrasound signal occurs upon reflection from the quartz. Such an interpretation makes it possible to neglect the divergence of the beam on the additional path, and the attenuation in it greatly exceeds the attenuation due to the broadening, so that it can be disregarded. 24(1) PHASE I BOOK EXPLOITATION SOV/3150

Vseosoyuznaya konferentsiya professorov i prepodavately pedagogicheskikh institutov

Primeneniye ultrazvukov i isledovaniya veshchestv, studiy konformatsii, vyznaniya i primeneniya ultrazvukov. Analizy i Substantsiy. Prezentatsiya na All-Union Conference of Professors and Teachers of Pedagogical Institutes, Nr 7) Moscow, Izd. MOPI, 1958. 283 p. 1,500 copies printed.

Tech. Ed.: S. P. Zhitov; Eds.: V. P. Mozdrev, Professor, and B. B. Kudryatsev.

REMARKS: This book is intended for physicists, technicians, aeronautical engineers and other persons concerned with ultrasonics.

COVERAGE: The book contains twenty eight articles which treat ultrasonic phenomena in five general categories: 1) historical data on the development of ultrasonics in the Soviet Union over the past forty years; 2) the speed of sound in suspensions of varying concentration and number and type of components and the relationship between sound velocity and the compressibility of electrolytes; 3) ultrasonic investigations of physical and chemical properties of materials and the determination of physical and chemical constants, e. g. density of aqueous solutions, adiabatic compressibility, molarity of solutions (with given temperatures), viscosity, surface tension, saturation pressure and also ultrasonic investigation of the carbon content and petrographic state of coal; 4) industrial applications of ultrasonics, e. g. emulsification of reagents, cleansing of textile fibers and enhancing the acceptability of some synthetic fibers to dyeing, etc.; and 5) apparatus which produce ultrasonic waves. No personalities are mentioned. References accompany each article.

TITLE: Research by the Pulse Method Along the Saturation Line  
on the Absorption of Ultrasound in Ortho- and Metaxylols  
(Issledovaniye pogloshcheniya ul'trazvuka v orto- i  
mitaksilolakh impul'snym metodom po linii nasyshcheniya)

PERIODICAL: Sbornik stud. nauch. rabot po yestv.-matem. tsiklu.  
Mosk. obl. ped. in-t, 1956, Nr 1, pp. 32-38

ABSTRACT: The pulse method used differed from the methods de-  
scribed previously. Here a quartz crystal generating bilateral  
radiation and two (instead of one) reflectors disposed at fixed  
distances along both sides of the crystal radiator were used.  
Absorption was determined by comparing the amplitudes of the  
pulses received from the reflectors. The absorption factor of  
orthoxytol was measured at the frequency 7.6 mc and in the tem-  
perature interval 19.5° to 325°, and for metaxylol at the fre-  
quency 15.1 mc and in the temperature interval 17° to 275°. It  
was determined that the absorption factor relative to the square

Card 1/2

Research by the Pulse Method Along the Saturation Line (Cont.) 112-2-4764

of the frequency increases in the whole temperature interval. The space viscosity and that part of the absorption due to drift viscosity (Stokes absorption) were calculated from the experimental data. It was determined that qualitatively, absorption determined experimentally and absorption as calculated by the Stokes law methods did not agree in the whole temperature interval. The Stokes absorption was less than the absorption determined experimentally. In the entire temperature interval, absorption determined experimentally for metaxylol is somewhat higher than in the case of orthoxyiol at the same temperatures.

Title : Investigation of the Absorption of Ultrasound in Ortho and Meta Xylols by Pulse Methods, Using the Saturation Line.

Orig Pub: Sb. stud. nauchn. rabot po estestv. matem. tsiklu Mosk. obl. ped. in-t, 1956, 1, 32-38

Abstract: A pulse method was used to measure absorption of ultrasound in ortho and meta xylols. The measurements were in an autoclave based on the saturation line in the temperature interval from 20 to 300°.

It was established that over the entire temperature interval the experimental values of the absorption are one order higher than the Stokes values. The coefficient of absorption for meta xylol is somewhat greater than that of ortho xylol for equal temperatures.

(Patent of the German Democratic Republic, class 24b 8/03, no. 20898, 17.II.61)

*Text:* A patent has been granted for the design of an atomizing burner (fuel injector) ensuring efficient combustion of liquid and gaseous fuel (see figure). To shift combustion from liquid to gaseous fuel, the fuel-feeding tube (5) and the sleeve (6) intended for combustion of liquid fuel must be replaced by the corresponding feeding tube and sleeve for gaseous fuel. These components are replaced by removing the cover (10) screwed to the burner body. The helical channels (7) and (7') are designed for whirling the streams of primary and secondary air

*M*

\*Removal of Surface Oxides by Pickling. F. N. Aleshin and S. D. Zigmolov. (*Metallurg (Metallurgy)*, 1936, (2), 55-59).—[In Russian.] Pickling in sulphuric acid proceeds slowly for brasses, and does not effect sufficient removal of oxides for phosphor-bronze and Constantan. Addition of potassium nitrate considerably improves and intensifies the action of the pickle on brasses and phosphor-bronze, whilst further addition of sodium chlorate ensures a satisfactory cleaning of Constantan. The best temperature is 80°-100° C. To remove the copper sulphate film from the phosphor-bronze or Constantan a mixture of sulphuric and nitric acids is used.—N. A.

\*Experiments on the Working of Manganese into Wire. S. D. Zhitnikov (Metallurg (Metallurgy)), 1933, (1), 83-92. (In Russian.) A large ingot of 33-34 kg. is cast at 1080°-1120° C. into a cast iron mould (temperature 120°-150° C.) and hot-rolled at 700°-810° C. into a 7-mm. wire, which is finished at 550°-600° C. The wire is drawn at a speed of 35-40 up to 75-82 m./minute. Hot-rolled and drawn wire of 3-4.5 mm. is annealed at 750°-800° C., and thin wire (1.0 mm.) at 700°-730° C. The best pickle is 10-15% sulphuric acid at 40°-60° C. The changes in the properties of Manganese wire with annealing temperature are given in tables and a diagram. -N. A.

*Investigation of the Optimum Conditions of Crucible Melting and Casting of Duralumin.* N. D. Zingulev and N. M. Nadejkin (*Metallurgy (Metallurgy)*). 1932, (8), 113-120; (9), 67-74; (10-11), 60-69; (12), 58-60. [In Russian.] The following defects in castings have been investigated: gas bubbles, oxide inclusions, dark spots of liquidation nodes, setting friability. From melting and casting tests on Duralumin bolts and sheet the following conditions have been evolved: A carefully cleaned and slag-free crucible is melted and batches of alloy, then with rods of aluminium, the charge is melted is complete, the bundles of clean scrap cuttings are added. When melting is complete, the temperature is raised to 740°-760° C., the crucible removed from the furnace, the surface of the metal cleaned of slag and impurities, and zinc chloride (0.10-0.15% by weight of the charge) added; the requisite addition of magnesium is then made and this is followed by a second zinc chloride (0.03-0.05%) treatment. The alloy is cast at 685°-705° C. Sheet moulds are cleaned with Chamotte brick, then dressed with chalk and pre-heated to 100°-180° C. before casting. Bolt moulds are dressed similarly, but preheated only to 40°-60° C. Pouring is done in a thin continuous stream along the narrow wall of the horizontally placed mould, which is gradually changed to the vertical during pouring. The cast ingots are removed after 5 minutes. N. A.

TITLE: Correlation between the optic and electric characteristics of crystal phosphors. Report. Fourteenth Conference on Luminescence held in Riga 16-23 September 1966

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 4, 1966, 875-878

TOPIC TAGS: crystal phosphor, electric conductivity, potassium bromide, optic property, electric property

ABSTRACT: There have been relatively few theoretical and experimental studies of the relation between the optic (luminescence and absorption) and the electric (conductivity) properties of crystal phosphors. The present work was devoted to an extensive and comprehensive study of the electric conductivity of KBr (high purity), KBr:Ca, KBr:NaBr (mole percent  $10^{-2}$  to  $10^{-4}$ ), and KBr:NaBr (mole percent  $10^{-2}$  to  $10^{-4}$ ). There were obtained the temperatures of the glow curve peaks, the conductivity peaks and the bleaching peaks and the corresponding characteristics under photostimulation. The resultant experimental data are presented in a large table together with some comparative

Card 1/2

results of other investigators. The results are largely consistent with the mechanism of electron-hole recombination as hypothesized and developed in the work of V.V. Antonov-Romanovskiy, Ch.B.Loshchik and his group, M.L.Kata, I.A.Parfyanovich and his associates, and other Soviet and foreign luminescence physicists (numerous references are cited). The tabulated data are discussed from the standpoint of correlation between the optic and electric properties: in some cases the correlation is obvious and strong; in other cases it appears to be weak or absent. The authors are sincerely grateful to Ch.B.Loshchik and I.A.Parfyanovich for discussions of some of the questions mentioned in the paper. Orig. art. has 1 figure and 1 table.

AUTHOR: Zirap, V. E.

TITLE: Complex studies on the thermoluminescence and thermostimulated conductivity of alkali halide crystallophosphors

SOURCE: Vses. soveshch. po fiz. shchelochnogaloidn. kristallov. 2d, Riga, 1961. Trudy\*. Fiz. shchelochnogaloidn. kristallov (Physics of alkali halide crystals). Riga, 1962, 385-389

TOPIC TAGS: luminescence, phosphor, crystallophosphor, alkali halide, alkali halide crystal, thermoluminescence, conductivity, thermostimulated conductivity, potassium chloride, potassium bromide

ABSTRACT: Extending the previous studies on the optical and electrical relaxation characteristics (the luminescence brightness  $I$  and the conductivity  $\sigma$ ) for alkali halide crystallophosphors during thermal and photothermal deexcitation, the thermal luminescence and thermostimulated current in KCl, KCl - Tl and KBr - Tl have been investigated at 100 - 400K. A  $10^{-6}$  mm vacuum cryostatic chamber, its temperature uniformly rising at a rate of  $\beta_0 = 0.15 - 0.20^\circ/\text{sec}$ , was used for the x-ray excitation and thermal and photothermal deexcitation of the  $1.5 \times 13 \times 15$  mm specimens. The luminescence brightness

Card 1/2

CIP CODE: 121

ACCESSION NR: AT4016322

was measured by synchrodetection with a FEU-19 M photoelectron multiplier, and the thermostimulated current in the specimen was measured by the voltage drop in the inlet resistor of the electrometric direct current amplifier. The thermal luminescence curves for excited KCl, KCl - Tl and KBr - Tl showed several peaks between 100 and 400K accompanied by synchronous similar peaks on the thermostimulated current curves. The curves are given an extensive mathematical treatment. The ratio between the brightnesses of thermoluminescence and thermostimulated current is suggested as a characteristic of the course of a relaxation process. A conclusion is drawn that the luminescence of the examined crystallophosphors during thermal deexcitation is of recombination origin within the whole 100 - 400K temperature range. "The author expresses thanks to I. K. Vitol for guiding the work, Ch. V. Lushchik for considering some of the problems encountered, and I. K. Liyelpeter and V. Putny\*n' for technical assistance." TITLE: Excitation and de-excitation mechanisms of the recombination luminescence of alkali halide crystal phosphors

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, v. 25, no. 3, 1961, 377-379

TEXT: This paper was read at the Ninth Conference on Luminescence (Crystal Phosphors) held in Kiyev from June 20 to June 25, 1960. The thermostimulated current, the thermoluminescence, and the spectrum of thermoluminescence were investigated by comprehensive experiments, and it was attempted to clarify some problems of the complicated relaxation processes in excited alkali halide crystals. The thermostimulated currents and thermoluminescence excited by X-rays in KCl and KBr crystals were investigated. The crystals were either unactivated or activated with thallium. In the temperature range 110-340°K, all peaks of one effect corresponded to those of the other. This fact is seen as a proof of the recombination nature of the afterglow in the crystal phosphors investigated.

If this is correct one has :  $I/\sigma = \eta \beta p / e u$  (1). Here,  $p$  is the hole concentration in the recombination centers,  $\beta$  the probability of recombination of a free electron with a localized hole,  $\eta$  the yield of luminescence produced by recombination,  $e$  and  $u$  the charge and mobility of an electron,  $I$  the intensity of luminescence, and  $\sigma$  the electrical conductivity. An experimental determination of the relation (1) can give information on a multi-stage relaxation mechanism. Fig. 1a shows graphically the dependence of the intensity of luminescence on temperature; the temperature dependence of the thermostimulated current and that of the quantity  $I/j$  are graphically shown in Fig. 1b and Fig. 1c, respectively. A step-like decrease of this ratio is seen in the temperature ranges 110-190°K and 270-330°K. It is surmised - and the surmise is supported by data already known - that electron recombination takes place in the first range, and hole recombination in the second. Fig. 2 shows the temperature dependence of the intensities of different luminescence bands (whose maxima lie at 2.6 ev, 3.0 ev, and 3.4 ev) of a KBr-Tl crystal (0.5 mole%). The curves (a) show the X-ray luminescence (measured by cooling the crystal) and the curves (b) the thermoluminescence (heating rate: 0.2 deg/sec). This diagram illustrates the effect of change of the

recombination mechanism on the luminescence spectrum. The nature of the luminescence centers is not known and would require new experiments for its clarification. Ch. B. Lushchik is thanked for a discussion, and I. I. Liyelpeter for help in the work. There are 2 figures and 16 references: 12 Soviet-bloc and 4 non-Soviet-bloc.

AUTHOR: Zirin, G.

TITLE: Magnetic fields in solar prominences

PERIODICAL: Astronomicheskij zhurnal, v.38, no.5, 1961, 861-868  
+ 1 plate

TEXT: The Zeeman structure of  $H_{\beta}$  is discussed and a system is worked out for the calibration of measurements of magnetic fields in prominences using  $H_{\beta}$  instead of an iron line in the system of the magnetograph of KAO previously described (Ref.1: N.S.Nikulin, A.B.Severnny and V.Ye.Stepanov, Izv.Krymsk. astrofiz. observ., v.19, 3, 1958; N.S.Nikulin, Izv.Krymsk. astrofiz. observ., v.22, 3, 1960). A slit width of 1.5 mm had been used for the narrow lines, but this was increased to 2.5 mm and then to 4 mm (0.46 Å) for use with  $H_{\beta}$ . However, as some light scattering appeared, both slit width and dispersion were reduced. Prominences were first identified in  $H_{\alpha}$ , using the spectrograph, and then observed at several slit positions in  $H_{\beta}$ . Not all the observations were reproduceable. The Zeeman splitting of  $H_{\beta}$  has been considered by A.B.Severnny (Ref.2: Izv. Krymsk. astrofiz. observ., v.22, 67, 1960), but there is a slight error in his results. The author gives his own

results in the table where  $\bar{\omega}_A$  is the transition probability and  $S$  the Landé factor. The shift of the  $\sigma$  components is given by Eq. (1) in A. The instrument was calibrated by comparing recordings at the centre and the limb of the Sun (this introduces a line shift, due to Doppler effect,  $\sim 2$  km/sec). So long as the shift due to polarization is less than  $0.4 \text{ \AA}$ , the  $H\beta$  profile can be considered as a Gaussian curve. Slight errors will occur if the line is not centred accurately on the slit. Spectra of a prominence taken on the 6th December 1960 (Ref. 2: as quoted above) indicated that the Doppler half width of the line is  $0.5 \text{ \AA}$ . This was used throughout the investigation, introducing another small error. The observations will also be affected by motions in the prominences. The author describes several sets of observations which gave positive results.

4

November 5, 1960. This was the brightest prominence of the series. The value measured for the field was 740 gauss, diminishing as the brightness decreased. (The height of this prominence was  $\sim 1500$  km above the limb.)

November 7, 1960. Large quiescent prominence. Field  $\sim 100$  gauss.

Height  $\sim 30000$  km.

Card 2/

Magnetic fields in solar ...

30817  
S/033/61/038/005/005/015  
E133/E435

- November 8, 1960. Extensive active region. Field ~350 gauss.
- November 11, 1960. Large quiescent prominence. Field had values of up to 100 gauss from 40 observations. Height ~40000 km.
- November 19, 1960. Active prominence. Field ~100 gauss. In this case the field appeared to change sign.
- November 24, 1960. Two prominences were visible at the same time. One of these was investigated and had a field ~150 gauss.
- December 6, 1960. Active prominence. Field ~200 gauss. This was observed jointly with A.B. Severnyy and is described in Ref. 3: (Observatory).

It is concluded that prominences have magnetic fields. For active prominences this is ~200 gauss, for quiet prominences ~50 gauss. These fields must be force free. Acknowledgments are expressed to A.B. Severnyy and S.I. Gopasyuk for their assistance. There are 10 figures, 1 table and 3 Soviet references.

557. MEANS OF LOWERING THE INCIDENCE OF ILLNESS AMONG TEXTILE WORKERS. (Russian text) Zirin G. A. VRAC. DELO 1956, 7 (737-740)  
By means of various prophylactic measures (anti-influenza vaccination, attention to microtrauma, increased number of showers, control of tare and instrument standards, use of special palm-protectors, control of drinking water and food, sanitary-educational work etc.) the incidence of illness with temporary loss of working capacity has been lowered considerably in the textile factories of the Vladimir region.
